## PREFACE TO THE TRANSLAYION.

A work embracing the grass family as a whole, in all its aspects, enumerating the best known economic species and the uses which they serve, discussing their structure and morphology and their arrangement into tribes and genera with the characters of these pointed out in a manner emabling one to classify any grass which may come to his hand, is a desideratum in our literature and one which has long been felt by many. Such a work is the contribution made by Prof. Eduard Hackel, of St. Poelten, Austria, to that great German publication on the Natural Families of Plants (Die natürlichen Pfanzenfamilien) edited by Drs. Engler aud Prantl. Prof. Hackel stands without a peer among agrostologists ; his contribution, therefore, has an especial value and may be accepted as expressing the latest views of the highest authority.

The work here referred to contains so much of practical as well as of scientific importance and interest that its presentation in a form available to English readers seemed highly desirable. A further incentive to the preparation of an English translation was the fact that at this time particular interest in the investigation of grasses is being taken by the United States Government, and on all sides eager demands are being made for information relative to these plants. That this is so is not remarkable when we consider the unrivalled economic importance of grasses, furnishing as they do diaily food to man and the amimals upon which he is most dependent, as well as supplying a great variety of articles used in manufacture, the arts, and medicine. While the present work may not add to the interest in the sulbject already existing, it camot fail to afford information much desired.

With a view to increasing the value of the work aud reudering it more serviceable to private students and
general reaters, an introduction wherein is illustrated the manner of using the keys of amalysis in determining genera is given, and a full glossary and index are athled. It is hoped also that the tramslation will thas be mate more suitable for use as a text-book in our Agricultural Colleges, for which purpose the treatment of the structure, morphology, and physiology of grasses, given in detail and fully illustrated in Part I, renders the work especially well adapted.

Those familiar with the German will notice that in translation occasional liberties have been taken with the original by the omission of mimportant matter, insertion of head-lines, etc. Except in the accoment of the Bambusere, all matter enclosed in brackets has been added ly myself. A number of notes and observations: have been added by Prof. Hackel, to whom the mannscript was submitted for revision and approval before being sent to the printers.

Following the number of each genus there has been inserted, in parenthesis, its number in Bentham and Hooker's Generu Plonturum, facilitating reference to that work and at the same time showing the diversity between the systems of classification adopted.

With few exceptions the illustrations are from electrotypes of the original woodcuts obtained from the German publisher, Wilhelm Engelmam, of Leipzig. The figures illustrating the spikes of the cereals were redrawn from the imprints in the original and reduced nearly one half by photo-engraving. Figures 3 a and 91 are atditions, while figures 45 of 75 , and 78 were drawn especially for the translation and appear here for the first time.

Thanks are due Mr. Charles E. Smith, of Philadelphia, for his kind assistance with the proofs, and Dr. W. J. Beal, of Lansing, Michigau, and Mr. (. M. McClung, of Knoxrille, Tennessee, for their interest in the progress of the work and material aid in its pulplicat tion.

F. Lamson-Scribner.

## INTRODUCTION.

No introduction appears to be necessary further than to give for the benefit of those unfamiliar with botanical keys, an illustration of their use. For this purpose let us suppose that we have in hand a specimen of Orehardgrass. After examining it carefully and noting the characters presented by the inflorescence, spikelets, glumes, etc., we turn to the key to the tribes on page 34 , and read the characters under "A. Spikelets one- ravely twoflowered," etc. In our specimen the spikelets are 3-5.)Howered, so we pass to "B," ou the next page. The characters here-"spikelets 1-s (many) flowered, . . . rachilla articulaterl above the empty glumes, . . . with distinct internodes between the flowers" (flowering glumes)-are those of our plant, and we continue by reading the characters following " a," all of which apply, and then go on reading the characters following " $\alpha$." As those of our specimen are here included, the spikelets being upon distinct pedicels and disposed in a panicle, we proceed to the next section of the key; riz., "I. Spikelets one-flowered." As those in our specimen are :3-5-flowered, we pass on to "II. Spikelets $2-\infty$ flowered." Our Orchard-grass falls under this section, and as it possesses characters (flowering glumes longer than the empty ones, and with a short straight awn from the point) which exclude it from the next division, " 1 ," we try " 2 ," which leads us to tribe XI, Festuceæ, further described on page 135. Carefully comparing our plant with the more extended characters here given, we note their agreement (or disagreement, as would be the case if we had proceeded wrongly to this point).

Being satisfied that our plant must belong to the

Festucer, we now try to determine its geuns by the key which follows. The flowering ghmes are not "divided into three-to-many awn-like lobes," so we pass from "A" to "B" on the next page, where it says "Flowering glumes entire or two-toothed," etc. As those of Orchardgrass are entire, we continue with the next division of the key, "a. Rachilla or flowering glumes with long hairs which envelop the latter." There are no such hairs in our specimen, so we pass at once to "b. Rachilla and flowering glume naked or hairy, hairs much shorter than the glumes." These characters apply to our plant, and as it has plumose stigmas projecting from the sides of the flowering glumes, we pass from " $\alpha$ " directly to " $\beta$," the division having stigmas of this character.

In order to avoid repetition, we will simply quote from the succeeding divisions of the key that which it is necessary to read to complete the determination, placing in italies the characters excluding from any one of them the grass we are analyzing. All reference to the subdivisions under these last are of course omitted.
"I. Spikelets of two forms," etc.
"II. Spikelets all alike."
" $1^{\circ}$. Flowering glumes three-toothed," etc.
" $2^{\circ}$. Flowering glumes of some other structure." "* Flowering glumes one to three-nerved," etc.
" $\therefore$ F Flowering glumes 3-5- to many-nerved, with two or more of the upper glumes empty," etc.
"*** Flowering glumes five- to many-nerverd; each containing a $\nsucc$ flower or the upper with only a $\delta$ flower, or empty." (Exceptions noted.)
" $\dagger$ Leaves broad, lanceolate or ovate, with fine transverse veins between the longitudinal nerves."
$" \dagger \dagger$ Leaves linear or lanceolate, no distinct transverse veins."
" O Keel of palea winged," etc.
"○○ Keel of palea not appendaged."
> " $\Delta$ Empty glumes three to six at the base of each spikelet."
> " $\triangle \triangle$ Empty glumes two."
> "X Plants strictly diocious," etc.
> "XX Plants hermaphrodite," etc.
> " $\square$ Flowering glumes cordate at the base."
> "ロロ Flowering glumes not cordate at the base. . . . AA. etc." (referring to the next series of divisions in the key).

"AA. Spikelets closely imbricate, arranged in a linear, dense false spike."
"BB. Spikelets densely imbricate, crowded in short spikes," etc.
"CC. Spikelets in small fascicles which are united in a glomerate or interrupted panicle." "aa. Panicles one-sided. . . 252. Dactylis."

Our analysis by the key has thus brought us to the genus Dactylis, No. 252, and ou page 161 we find given further characters belonging to it. We learn here also that the genus contains but one species, Ductylis glomerata L. or Orchard-grass, its geographical distribution, that it is " a first-class fodder-grass, especially for heary, wet soils," that it is very productive, growing rapidly after cutting, and endures shade. There is also a figure, illustrating the inflorescence and a single spikelet, on page 102.

Orchard-grass was selected to illustrate the use of the keys not only because it is widely distributed, either naturally or in cultivation for hay, and therefore readily obtainable, but also because its analysis required such an extended use of the key. There are very many genera requiring much less reading in their analysis and possible of determination far more quickly. The manner of procedure is practically the same in every case. While the keys are in the majority of cases a certain guide in determining the genus, the statement made on
page 33 must be kept in mind when using them; for in the tribes as well as in the larger genera the characters given are of necessity subject to many exceptions.

Under each genus will be found its distingnishing characters not already mentioned in the keys, the mumber of species it embraces and their geographical distribution, also the names and uses of those species of marked economic value. The somewhat extended account given of the Cereals and Bambons, che to their special inportance, contains much of general interest.

# THE TRUE GRASSES. 

(GRAMINEE.*)

## PART I.

## STRUCTURE, MORPHOLOGY, AND PHYSIOLOGY.

Special Characters of the Order.-Flowers hermaphrodite, ravely unisexual, perianth none, in the axils of enveloping chaff-like scales or bracts (flowering glumes), wolitary or united into manyflowered spikelets ; one bract (palea) usually two-keeled and opposite the flowering glume; one very small scale (anterior lodicule) split to the base and usually herbaceous, above the flowering glume; rarely with another entire scale (posterior lodicule) above the palea; occasionally with the palea only, or even without that; rery rarely truly terminal.

Stamens usually in a whorl of three (rarely two) members, sometimes; in two alternating whorls: the number of stamens in a whorl is sery rarely either much increased, or reduced by abortion to one. Carpel single, standing opposite the palea. Ovary one-celled, usually with two lateral, rarely with three or one, styles. Ovule solitar'y, slightly camplotropous, without a funiculus and with the micropyle turned downwats. Fruit usually a caryopsis rich in amylaceous matter. The embryo, covered only by the pericarp, lies outside of the albumen at the front and base of it. Embryo usually small and straight with a shield-shaped cotyledon, in the anterior cavity or furrow of which lies the plumule, having several rudimentary leaves, and the radicle with its surrounding tissues.

[^0]Heri)s, rarely shrubs or trees, with closed-jointed stems (culms) and alternate, sheathing leaves. Sprikelets or solitary flowers nsually with empty chaff-like bracts (empty glumes) at the base, arranged in panicles or spikes.

Organs of Vegetation.-The Cclur-Grasses are either monocarpic or, more commonly, perennial by means of a rhizome which is formed by the cateuulate lowest internodes of the consecutive flowering culms and their leafy basal brauches. Aerial, woody, peremial stems occur only among the Bumbusere. Perenuial grasses may usually be recognized by the presence of sterile shoots which grow from the lowest joint of the culm or proceed from that of other similar shoots ; they often break throngh the sheath of the subtending leaf while yet buds (extraraginal shoots) or, more rarely, develop within the sheath (intraraginal). In the latter case the grass formus dense and sometimes large but always isolated tufts. For the formation of close turf (Grasnarbe), such as the meadows of wooded regions present, only grasses with extravaginal shoots are adapted, since these shoots, before they grow upwards, creep for a longer or shorter distance below the surface, and the rumers thus formed quickly fill up all the available interstices of the soil hy their ramifications. All grass culms hranch at least from the lowest modes, and these also lave the power of sending out secondary roots. Eren aside from the richly branched Bambusere, branches from the upper or from all nodes oceur in many tropical grasses, but in those of the temperate zone of the Old World this habit is rare. The culm is rarely filled with pith ie.g., almost all Andropogonere, many Panicere, etc.) ; it is usually hollow, the central carity resulting from the separation of the original pith cells which have ceased to grom, and the remains of these cells line the walls of the carity.

The Nodes.-The pith carity is always closed at the modes which are the larger or smaller swellings at the limits of the internodes. The difference between culm-nodes and sheath-nodes is constantly orerlooked, but ought to be carefully noted. The swellings that are risible externally do not belong to the culm,
but to the base of the leaf-sheath; they are to be found in all grasses (Molinia excepted), at least so long as the internode above has not completed its growth ; but when the base of the internode, the portion which remains longest capable of growth, is transformed into permanent tissue, one of two things may happen: the tissue of the sheath - node may remain turgescent and capable of growth, then no swelling is formed at the base of the culmjoint; or a true culm-

Fig. 1.- A, Fragment of culm of wheat with sheath-node, somewhat bent. $B$, Longitudinal section of the saine; sk, sheath-node; $h b$, point of insertion of the sheath. $C$, Andropogon; the sheath $s$ removed on the left side in order to show the culm-node, $h k ; ~ s k$, sheath-node. node may be developed from one to three millimeters above the sheath-node, assuming all the properties of the sheath-node (see below), and at the same time the latter shrivels up. This last is the case with all Andropogonere and Panicere, and many Pambusere, as well as with many single genera of other tribes (for example, Stipra, Eragrostis, Pappophorum, Arundo, etc.). The majority of Agrostidere, Avenere, Festucere, and Triticere have only sheath-nodes; and, finally, there are grasses without any distinct nodes, such as have their branches very thickly leaved, from the fact that in these the sheaths of several internodes overlap each other, as in many Bambusece.

The nodes are not, as is often supposed, to give strength to the culm; they are composed of a somewhat thin-walled parenchyma whose cells are strongly turgescent and through which run delicate fibro-vascular bundles with well-developed bundles of collenchyma on the outside. Their function consists solely in the erection of culms that have become bent down. The parenchyma of the node is geotropically sensitive, and as
soon as the culm is placed in a horizontal or oblique position the cells of the node on the side turned towards the earth begin to elongate, and consequently the lower side becomes longer, while the upper side is shortened and often wrinkled from the pressure of the opposite side; this continues until the upper internodes have resumed the vertical position. Several nodes, however, may share in this process at the same time.

Mimute structure.-In the tissues of the culm a larger or smaller ring of sclereuchyma is especially prominent ; it lies close under the epidermis, to which it is often joined by rib-like sclerenchyma bundles. Similar bundles accompany the fibro-vascular bundles both without and within, or even form a ring about them ; the great firmness of the culms is due to the mass of strougly developed sclerenchyma. In pithless culms the fibro-vascular bundles are usually arranged in two circles, one of which is on the inside and the other on the ontside of the sclerenchyma ring ; in culms containing pith other bundles are present, either scattered through the pith or arranged in indistinct circles. Each bundle contains two or three large, pitted vessels between which aud towards the centre is an air-passage resulting from the rupture of an old, ringed vessel, as is shown by the presence, here and there, of isolated rings. For other portions of the bundle, see explanation of Fig. 2.

The fibro-vascular bundles run parallel in the internorles; the superficial ones join those of the lower internodes tirectly, the others take the form of a shallow arch beuling towards the centre (in culms with pith), where they pass through several internodes, aud finally beul outwards to join the superficial ones. In the nodes the bundles cross and interlace hy means of small and short cross-bundles, which pass from the axillary shonts or buds towards the centre. In this way arise the diaphragms or plates of tissue which separate the pith cavities of the internodes.

The Leaf.-The leaves of grasses usually alternate in two ranks $180^{\circ}$ apart, and those near the ground often form tufts or even fan-shaped bunches through the non-
development of the internodes. Such tufts are also fomd upon the upper nodes and rumers of some grasses, for example Sporobolus, Cynodon, Eluropus, and Chloris, whenever a well-developed internode is followed by $2-4$,

Fig. 2.-Cross-section of a fibro-vascular bundle from the culm of Maize ( $\times 550$ ). $p p$, Surrounding parenchyma ( $\alpha$, outer side; $i$, inner side). $g g$, Pitted ressels: $l$. air-passage with isolated ring, $r$, from a former ring-vessel; $v v$, sieve-tubes. The shaded cells in the circumference are those of the sclerenchyma threads: those between $g$ and $g$ are very narrow pitted vessels; $s$, a spiral ressel. (After sachs.)
shortened, nodeless ones. Every branch begins with a two-keeled, rarely (Cynodon) two-cleft, membranous prophyllum with its back towards the main axis, and is followed by the other leares in such a manner that their median plane crosses with that of the prophyllum and the leaf in whose axil the branch originates. The suc-
cessive shoots are antidrom [a technical term of German morphologists], -that is, if the first leaf of one falls to the left of the subtendiug or supporting leaf, that of the next falls to the right, etc.,-so that the first leaves of all branches fall on the same side of the main axis. The same holds true, of course, in case of secoudary branches rising from the axils of these leaves even when the sub)teuding leares are undeveloped, as is usually the case in the inflorescence.

Every foliage leaf consists of at least two parts, the sheath and the blade. A true petiole is inserted between these only in a few broad-leaved, tropical grasses (Plurus, Phyllorachis, some Ischuena, many Bambusere, etc.). The blade is always absent in hypophyllia and propliylla, and in the floral leaves (called glumes or bracts) it is either absent or transformed into a narrow bristle-shaped appendage, the awn, which is sometimes twisted or bent. The sheath surrounds the culm like a tube, and the two edges usually overlap in front, the covering edge being somewhat raised. In the successive internodes the raised edge is alteruately on the right and left. The sheaths of numerous grasses (all Sesleriere, many Pore [pratensis L., trivialis L., alpina L.], Bromus [inermis Leyss., erectus Huds.], Briza, Melica, Dactylis, (flyceria flutans Brown, etc.) are, on the contrary, perfectly closed, but the young and still included inflorescences, by forcing their way upward through these narrow chamels, usually cause them to split. The sheath matures earlier than the internode above its insertion, and consequently its stiffening tissues, viz., the sclerenchyma bundles, are perfectly formed at the time when the enclosed interuode in its basal portion is yet tender and without firmness. The sheath is, in cousequence, a very important protection for the young internodes, and this function is performed even by the bladeless first leaf in breaking through the ground with its hard point; if the latter be cut away, the enclosed shoot is not able to stand upright and reach the surface.

The Ligule.-At the point of mion between the blade and sheath there is at the inside an erect prolongation
of the latter (ligule) which is usually membranous, but may be herbaceous at the sides. It originates from an additional growth of the sheath upwards at the insertion of the blade. If the blade is narrower than the sheath, then at least the side portions of the ligule are of the same character as the sheath, and are furnished with fibro-vascular bundles, while the centre, upon which the blade rests while in the bud, remains membranous (see Fig. $3, B)$. If the blade is the same breadth as the sheath, then the entire ligule is membranous (Fig. 3, A).

Fig. 3.-Point of separation of the sheath (s) and blade (spr). A, in Dactylis glomerata L. $B$, in Ammophila arumdinacea Host. l, Ligule. C. Flowering glume of Bromus Alopecurus Poir.

In the flowering glumes of many grasses-Avenct and Bromus, for example-whose blade has developed into an awn (Fig. 3, C'), the ligular portion is much developed, and the awn is then said to be on the back or dorsal (see above). Flowering glumes with terminal awns have no ligular portion ; there are also analogons cases in ordinary leaves, for example in Panicum Crus-golli L. In many grasses, especially in many of the Chloridere, the ligule is transformed into a fine hairy fringe. The ligule always embraces the culm very closely, and Schlechtendahl thought that its office was to keep rain or water from getting between the sheath and culm.

The Leaf-blade.-The blade is usually elongated, narrow linear or linear-lanceolate, rarely, and only in tropical species, ovate-lanceolate, elliptical, cordate or sagittate (Phyllorachis, etc.). In the bud the leaf is simply folded (rarely plicate folded, as in Panicum plicatum and related species) or rolled up from one side, the other half being somewhat broader, and the sides by which
the rolling up commences alternating from right to left in the successive leaves.

Leaf Torsion.-The adult blade often exhibits torsions; all the broader leaves of Festuca, Holcus, Culamugrostis, etc., are twisted to the left, at least in the upper portions, those of Secule, Triticum, ete., to the right, and of many dvenere in both directions, being twisted in one direction above and the other below. The leaves of many woodland grasses (Milium effusum L., Brachypodium silunticum R. \& Sch., Festuca silv. Vill., Melica altissima L., Pharus latifolius L.), also of some narrow-leaved species (Gynerium argenteum Nees., Ammophila arundinucer Host.), are turned $180^{\circ}$ at the base, so that the upper and under sides are reversed. In this case the stomata are only upon the original upper side. This phenomenon is probably due to the influence of light (heliotropism) ; and this is more certainly true in regard to the remarkable sleep-movements exhibited by the leaves of Olyre Guyanensis (Strephium Guyan. Brongn.). In the day-time the leaves of this grass stand out from the culm, and the upper surfaces are turned upwards, but at night they lie close to the culm and their surfaces are at an angle of $90^{\circ}$ from the position during light. This torsion is effected by means of a very short petiole.

Nervatiou.-The fibro-vascular bundles (nerves) of the blade either enter it separately and then run parallel, or a number at first unite with colorless parenchyma to form a strong midrib at their entrance to the blate, later the single bundles separate one at a time and pass towards the edge of the leaf. This arrangement gives an especial firmness to the base of the leaf, which has to bear the weight of the entire blade. Maize, Sorghum, etc., are examples of this arrangement, which is especially frequent in tropical grasses. The fibro-vascular bundles, at least the primary ones, are accompanied on the lower or on both sides by bundles of sclerenchyma which are frequently united into rings; this happens especially in those species with rush-like leaves, and gives them their very stiff blades. The epidermis contains very irregular cells whose walls in many cases
contain much silica. The bands of upper epidermis that lie between the nerves often present wedge-shaped cells (" bulliform" ceils), arranged in the form of a fam, whose growth and expansion canses the blade to open out; in those leaves which are folded in the bud these cells are only to be found on each side of the midrib). In grasses that do not have such fan-shaped cell-groups the blades remain always folded or rolled up, or at most open but a little, and consequently appear thread- or rush-like (many species of Stipu, Festuct, and Nardus). In others, especially in many of the Steppe grasses, the

Fig. 3a.-Transverse section of the primary vein of Festuca elatior, var. arundinacea. $S c$, sclerenchyma; $P$, colorless parenchyma; $C b$, bulliform cells. (After Hackel, Monog. Festuc. Europ., Tab. II. Fig. 6.)
blades roll up whenever these cells lose their turgescence by excessive evaporation, but become flat again, or at least half open, as soon as the air becomes moist. This rolling up of the blade acts as a protection against excessive evaporation ; for the lower side, which is then alone exposed to the air, has especial protective arrangements against transpiration in its strong cuticle, sclerenchyma masses, etc.

The stomata of grass leaves usually stand in longitudinal rows and are surrounded by four cells; two large secondary cells project beyond and cover two long and narrow guard-cells, which are usually much narrower than the first.

Inflorescence.-Distinction must be made between the special inflorescence, the spikelets-which will be referred to farther on-and the entire inflorescence. The latter arises by monoporial division of the upper portion of the culm, and the branching may be in different degrees: when the primary branches form single spikelets and the lowest glumes of these are apparently sessile upon the main axis, the inflorescence is a spike (which is really compound) ; if the bases of these primary branches are naked, forming a pedicel, it is a ruceme; and if the spikelets are only upon secontary or farther divided branches, a panicle. The inflorescence is yet more complicated in many Andropogonere, Punicere, and in Maize, where the branches of the panicle bear racemes, whose spikelets, however, are borne partly on primary and partly on secondary branchlets of these racemes. The primary branches of the whole inflorescence are most frequently alternately two-ranked, aud more rarely (as in many Andropogonere, Punicere, Sporobolus, Eirugrostis, etc.) spirally arranged ; in the latter case they are often in whorls of from 2 to 4 members. The two-ranked arrangement is often altered by the more rapid growth of one side of the main axis (the side which is turned more away from the earth in the bud) ; the spikelets accordingly move toward one side and the inflorescence becomes one-sided, as is especially noticeable with the panicles of Dactylis and Cynosurus, and the spikes of the Chloridece.

This appearance is intensified by the relations of the secondary branches. According to the laws of antidromy (see page 6), the first secondary branches all fall upon the same side of the culm; since these mostly arise near the base and are again branched, this side of the main axis appears to be much richer in spikelets. Where the secondary branches also arise near the base anl are as strongly developed as the primary ones, the inflorescence regains a symmetrical appearance (Poa prutensis, $P$. triviclis). If the branches are short and lie close to the main axis and all the internodes of the branches remain short, the result is a cylindrical, false
spike or spike-like panicle (Phlerm, Alopecurus, etc.). In this case the primary branches are frequently grown to the main axis, and consequently the secoudary branches appear to be arranged spirally ou this (Pheum pratense L.), while Ph. Bcehneri Wib. has free primary branches.

The supporting bracts of the branches of the inflorescence are usually entirely aborted, but on the lowest branches they often occur as rudiments, rarely as wellformed glume-like scales (Sesleria), and still more rarely (Anomochloc, Phyllostachys) they are well developed on all the primary branches. Frequently the leaf of the culm or branch which stands next to the inflorescence is in the form of a sheath enclosing the spikelets (Zert of, Coix, Lygeum, etc.). The false panicles of some Audropogonece (Andropogon, Nurdus, Fig. 19) are interspersed with leaves, and arise from brauches supported by the upper leaves of the culm, these branches in turn bearing leaves and branching again.

The Spirelet.-The spikelets consist of an axis composed of short articulations, two-ranked chaffy leaves (glumes) (spiral in Streptocheeta only), the first 1 to 6 of which (usually 2) are sterile and known as empty glumes or glumes only, while the following one to many glumes (flowering glumes or lower paleæ) bear in their axils a very short branch which begins with a bractlet called palea (or superior palea) with its back turned towards the axis, and ends with a flower.* The end of the axis of the spikelet is either visible beyond the upper Hower (Fig. 84) or its growth is arrested early ; in many one-flowered spikelets it is not at all visible even in the earliest stage of them, and consequently the flower is situated upon the end of the axis. In this case there is no longer a true distinction between empty and flowering glumes and paleas, for the entire spikelet represents a single flower with many

[^1]bracts (Anthoxanthum, Oryza, Andropogonece). Howerer, it is possible to demonstrate a perfect series of stages by which one-flowered spikelets with a distinctly lateral flower pass over into those with terminal flowers; cousequently a palea and flowering glume can be distinguished in the latter by analogy.

The uppermost glumes of a spikelet are not infrequently empty, and in this case they are usually dwarfed

Fig. 4.-I, Diagram of a many-flowered spikelet of Avena, Poa, Triticum; A, axis (rachilla). II, Diagram of a flower of Bambusa with flowering glume and palea; $l_{1}$, nosterior lodicule. or anomalous (Melice, Fig. 80). The empty glumes are lacking (Coleanthus), or scarcely visible as rudiments (Leersin), in only a few genera; there is rarely but one, most frequently there are two, and more rarely more than two, present. In the latter case those following the second are described by most authors as sterile flowers (e.g., in Panicum, Andropogonere, and many Bambusert), a plan which we shall not adopt in our descriptions. It is true that in closely related species (of Panicum, for
example) the third glume of some is empty and therefore a sterile glume, while in others it bears a $\%$ flower or merely a sterile branch with the palea, in which case it becomes a flowering glume; but this by no means makes all Panicums two-flowered, any more than we would call Lencojum vernum a three-Howered plant because both of its empty bracts bear flowers in other species of the same genus. In most and the best works (e.g., Kunth's, but not Bentham's) this third glume is called a neuter Hower ("flos neuter"), a term whose meaning should be always present to those desiring to use these works. The empty glumes are often very like the flowering, but are seldom awned. The flowering glumes assume many forms and are frequently awned; they almost always have a middle nerve. At their point of insertion they frequently extend dowuwards a little on the axis of the spikelet; this portion which is grown to the axis is separated from the free portion by a more or less distinct furrow and is called the callus; it occurs also upou many empty ghmes (Heteropogon contortus R. d Sch.), is frequently hairy, and in the fruiting glumes serves to fasten them to other objects. (Compare Stipu, Fig. 44, cul.) The palea, which with its enclosed flower stands opposite to the flowering glume, does not beloug to the main axis of the spikelet, but to the branch which bears the flower. That this relation of parts may be gradually obliterated in the one-flowered grasses, and that the palea may be moved back upon the main axis, has been explained above. As long as an axis or a rudiment of one, at least in its earliest stage, is visible beyond the palea, this latter possesses (like the prophylla of the culm-branches) two keels, or at least two lateral nerves, without a midrib; only when all trace of the axis is absent does the palea become from one- to many-nerved (with a midrib) or nerveless. It is almost always of a more delicate texture than the flowering glume, its edges are usually turned in, and it has a furrow instead of a midrib. The prophyllum of the culm-branches has no blade, and the palea resembles it in being almost always (excepting Amphipogon) awnless ; and as the former
is sometimes split in two parts (Cymodom), so the palea is often split at the time the fruit is mature (many Sporobolus and Triticum monococeum L). This state has been understood by some authors as originally hifoliate, and false genera have been established upon it by some (Dinchyrimm Griseb, etc.). The palea is completely aborted in many Andropogonere and species of Agrostis.

Opposite the palea, and therefore above the flowering glume, are, in most grasses, visible two small delicate scales (lodicules) ; they stand close together, their front edges touching, their hases somewhat grown together and swollen with sap at the time of flowering (cf. Fig. 28, $F$; Fig. 63, $G$ ). They are usually considered the two anterior members of a rudimentary perianth, whose posterior member (the posterior lodicule) is developed in Stipu and many Bambusere. The author has endearored to prove that the anterior scales represent the halves of a leaf which sometimes (Melicr, Fig. 80, F) remains undivided, and can be regarded as a secoud, and the posterior scale as a third, palea.* The anomalons condition of these palcas (in respect to the ordinary palea) is explained by their biological properties. The rapid swelling of the bases at least, causes the separation of the flowering glume and palea, and consequently the opening of the flower. In grasses where they swell only a little the spikelets open but slightly, and where the lodicules are membranous or entirely lacking the spikelets remain entirely closed at the sides, and the reproductive organs protrude only at the apex (compare Anthoxenthum, Alopecurus, etc.). The absence of the locticules is not necessarily a case of abortion; for if they are bractlets, a decrease in their number (as in the Juncaces) is not very remarkable. Their large number (8 or more) and apparent spiral arraugement is striking in Ochlondro: here their relations have, however, still to be studied in living material.

All the leaf forms that have so far been mentioned in the spikelet do not really belong to the flower;

[^2]they all lie (Streptocheta and perhaps Ochlundra excepted) with their merlian lines in one and the same plane, and, as in the branches of the culm, this crosses that of the subtewding bract, which in this case must be supposed. Where the entire inflorescence ends in an apical spikelet its glumes are uaturally arranged like the supposed subtending bract, and therefore cross those of the lateral spikelets (e.g., Triticum sativum Lam.). Several genera related to Lolium form an exception to this ; in these genera the median plane of all the glumes coincides with that of the subtenting bract. Hordeum and Elymus form another, hut only an apparent exception ; in these not only do the empty glumes of the 2-3 lateral spikelets converge in front, but their median plaue crosses that of the flowering glume at different angles $\left(30^{\circ}-90^{\circ}\right)$. All these variations depend upon mechanical causes, and are ouly to allow the glumes of the double or triple spikelets to fit into a given space, since the normal arrangement is present in the solitary terminal spikelets of some species of Hordeum (H. crinitum Desf., etc.) and all species of Elymus.

The succession of the flowering of the spikelets should be especially noticed, since in panicles it usually occurs about in that order in which the spikelets emerge from the sheath of the upper leaf; therefore the terminal spikelets of the panicle and its branches flower first, and from there downwards. In spikes the spikelets sitnaterl just above the middle usually precede the others, as they are best developed. In single spikelets, flowering passes from below upwards ; in Panicere and Andropogonere only, if a terminal of stands below the apparently terminal $\wp$ one, it blooms later than the latter.

Organs of Reproduction.-The Stamens.-The androcium consists of from one to two whorls, each composed of from two to three members; the stamens are rarely (Pariana, Luziola, Ochlandra) more than six (to forty), and in this case apparently spirally arranged. The first stamen of the outer, and usually the only, whorl alwars stands above the flowering glume; this is distinguished by the fact that it is earlier and
more strongly developed than the other two, which stand in front of the keels of the paler. On the other haud, this rery stamen may be aborted and only the two posterior ones remain (Diarrlena, Oithoclucur); where the entire whorl is reduced to a single stamen (Uniolc, Cinnc, many species of Festuce anct Andropogon, etc.) this is generally the anterior one, but in Elytrophorus it is posterior. We find a typical two-membered whorl in Inthoxanthum, Hierochlon $\underset{\sim}{\text { a }}$, and Crypsis; here the stamens lie in the mid-line of the glumes, but in Colementhus they alternate with the glumes. Two alternating whorls occur in the majority of the Bumbusere and in many Oiyzere. Generally both whorls have three members, but in Tetrarhena and Microlena they have but two. Since the following (single) carpel always stands above the flowering glume no matter whether the stamens are in one whorl or two, when only one is present the inner must be supposed.

The stamens always have slender, distinct, rarely (Streptochretu, Gigantochloa, Oxytenanther(1) monadelphous filaments that are composed of thin-walled cells. In the closed flower they are very short, but at the time of flowering they elongate by the very rapid extension of the cells. They remain straight for a time (Phlerm), or suddenly become tipped over in such a way (Triticum) that the main mass of the pollen is emptied.

The elongated, usually narrow-linear anthers have a very fine comective and are versatile; that is, the filament is attached below the middle ( $\frac{1}{4}$ or $\frac{1}{3}$ ) by a tapering end. This circumstance assists in the scattering of the pollen by the wind. Rarely the filaments are attacherl at the base of the anthers (Coleanthus). The polleu-sac usually opens by a longitudinal split which proceeds from above downwards, more rarely (Amdroporgoneret by a hole at the apex, which is often contimed into a split. The pollen is rery finely granular, spherical, and perfectly smooth. It is discharged in very abundant masses, and scattered by the wind (except in the cleistogamic species).

The Pistil.-The pistil arises from a single carpel
which always stands in the median plane of the spikelet towards the front. It is composed of an ovary with one ovile and 1-3 styles, each with one stigma; the stigmas may also arise from a single style or directly from the ovary. If but oue style with one stigma is present, it corresponds to the midrib of the carpel, and is to be regarderl as the blate, and the ovary as the sheath (Jorrthus) Miany times an apparently simple style arises from the mion of two (Zell, Enchlenu, and many species of Pemnisetrm). If there are, as is hy far the most frequent, two styles or two sessile stigmas, they are lateral, never posterior, heing either on the sides or the front of the carpel. Both may be regarded as the developed side portions of one lamina (or hade), the central part of which is at the same time suppressed; they are therefore amalogons to the anterion loricules. If the middle portion is clevelopect, we have the three (free or partly grown together') styles of many Bombusere and Streptocheta, where the third style conserpuently lies in front. In many pistils (Brizu mertion there is frequently a rudiment of a posterior strle offen provided with a stigma) which may be explained as a commissural form like the ligule of Ifelica miftore Retz., which is opposite the hlarte and rises from the unitert edges of the sheath. The stigmas, easily recognizahle by their papillate cells, are rarely simple (harbellate) (Figs. 73, 74), but are msually spirally branched; in the latter case the branches either come off in all direc-tions-aspergilliform (Figs. 15, 18), -or only from two sides-phmose (Figs. 80, 89, 95). From these branches rise smaller papillie. The entire system of branches has of course a large surface, and is especially arranged to catch pollen carried by the wind.

Pollination.-As has been staterl, grasses are fertilized hy the wind. Monocions and dixecious species are not numerous; but not a few are polygamons imany Andronogonere and Permicere), and in these the $\geq$ flower of a spikelet always blooms later than the hermaphootite, so that its pollen effects cross-fertilization upon the stigmas of other sprikelets or other individuals. There are also many arrangements for cross-fertilization
among the entirely hermaphrodite species. Many genera (Alopecurns, Anthocunthum, Pemisetum, Spuifinut are strongly proterogyuous; in most cases, lowever, the authers protrude earlier and discharge the greater part of their pollen, especially by turning over suctileuly, before the stigmas are visible. When these emerge at the sides of depeutent or nodding spikelets they are directed upwards, and consequently only the pollen from flowers situated higher up can come in contact with them. More rarely the stigmas project from the apex of the spikelet, and then mainly in the proterogynons and monorinus species. In some hermaphrodite flowers cross-fertilization is so much the rule that tliey have lost the power of effectual self-fertilization, as in Rye. In the majority of cases, however, both kinds of fertilization seem at least to be possible; for example, the species of Wheat are usually self-fertilizen, but may also be adapted to cross-fertilization, since their glumes are open above, the stigmas project laterally, and the anthers empty only about $\frac{1}{3}$ of their pollen in their own flower and the rest iuto the air. Cross-fertilization is much more rare and difficult in Barley, and in certain races like the six-ranked, the short-spiked two-ranked, and the peacock Burley, the flowers, especially in our climate, never open, and consequently cross-fertilization is made impossible. Again, Leersia oryzoides Swz. and Amphicarpum Purshii Kunth, are strongly cleistogamic ; in both there are two kinds of inflorescence ; the conspicuons terminal panicle of the culm is perfectly sterile, but the lateral inflorescence of Leersia, which remains covered by the sheath, is abundantly fertile ; in Amplicorpum the fertile spikes are upon short scapes close to the ground, and seem to be fertilized aud mature under ground. Diplachne serotina Link., Danthonia spicata Beauv., Stipu juncer L., etc., are also cleistogamic species.

The Ovule.-The ovule is grown to the veutral suture of the carpel without a funiculus. The point of union may be coufined to a narrow place at the base, or may vary so far as to reach to the other end of the ovule (Fig. 6, A). The orule itself is hemitropous (slightly campylotropous),
with its micropyle turned downward and outward. It possesses two integuments (Fig. 6, $A, i_{1}, i_{2}$ ), the outer one of which hats very delicate walls and forms a conductive tissue for the pollen-tube upon the anterior side. It disintegrates soon after fertilization.

The embryo-sac (Fig. 6, $A$, es) grows rapidly after fertilization at the expense of the tissues of the entosperm, so as to leave only 1-2 layers. At the same time it becomes filled with considerable albumen in whose cells, the outer layer excepted, is deposited an abondant supply of starch. The orule meantime grows rapidly in length and later also in breadth, and finally fills the cavity of the ovary so completely that any further growth canses it to grow to the walls, aud this fails to happen only in a few cases. The embryo is at first a many-celled club-shaped body whose vegetative point is situated in a lateral depression; the portion of the embryo above this depression becomes the cotyledon, which farther expands, becoming shield-shaped. Then the borders of the depression in which the vegetative point is situated rise up in the form of a collar,-the begimning of the first sheath-like leaf, hypophyllum, and opposite to it, later on, is developed the first foliage leaf. The initials of the main root lie deep within the lower half of the young embryo, so that the surrounding tissue grows with the root for some time until the latter separates itself from the tissue around it by forming a cleft. But the entire radicle is still imbedded in it, and not earlier than the seed germinates the root first breaks throngh this tissue, called the coleorlizu or root-sheath (compare $c$ in Fig. 6, $L, N$ ). Upon the sides of the main radicle $2-4$ secondary radicles are occasionally situated $\left(w_{1}, w_{2}\right.$ in Fig. 6, $F$ ), and on the other end of the axis the beginnings of the foliage leaves increase in the bud to 3 or 4 , so that the germ of the grass at the maturity of the seed has reached a high degree of development.

Fruit and Seed. -The fruit of most grasses is a caryopsis the thin pericarp of which is grown fast to the seed. The pericarp here answers the purpose of the testa, which is only very feebly developed; it gemer-
ally consists merely of a few cell layers; ome, a very thick-walled epidermis, and several of tolemably thinwalled parenchyma with delicate fibro-vascular humdles, and an imer epidermis that is frequently indistinct. It contains no amylaceons material, and when the grain is ground it, together with the adjacent layer of alhmmen, is removed as bran. In many grasses the pericarp mites more or less with the bracts, growing especially to the palea, seldom to the flowering glume. Those caryopses atherent to the bracts (e.g., most barleys) must mot he confused with those in which the bracts are close aromul thie fruit but not grown to it (for example, in Spelt, Tritichm spelter L., whose frnit is often spoken of as adherent). After long soaking in water the bract may with care be remored even from the atherent frnit.

The following fruit forms are more rare in grasses: Utricle-the pericarp thin, dehiscent, free from and surromnding the seed; for example, Sporotolus (Fig. $51, l_{i_{1}}$, $h_{i z}$ ), Elensine (Fig. 71, li), Crypsis, aul Heleochlow: Noutfrints in some Bombuserp (Iendirocrlamus, Psendostrchyum, Schizostachynm, ete.) and in Zizniopsis: Berries, often as large as apples, as in the Brembusere, Melocotrmins, Melocrmar, and Ochlendic(. The berries of Melocumn bumbusoides are ofteu from $\delta$ to 13 ceutimeters in diameter and are edible.

Upon the caryopsis is a place where the embryo lies

Fig. 5.- A, Fruit of Agrostis sesquifluru, Desk., with punctiform hilum: B of Pennisetum Chilense, with an oval-borderell one: $C$, of fromus Mfung Desv.. with a linear hilum. (After Desvaux Gram, and Cyp. Chil.) covered only by the pericarp and plainly visible on the outside (Fig. 6, B). This place is upon the front side (that is, the side facing the floral glume) of the base of the fruit. Opposite to it, or on the posterior side, the fruit hears a more or less clear, sometimes punctifor'm and sometimes elongated or linear mark, the hilmm, the phace where the seed was fastened to the wall of the ovary (Fig. 5).
since the form of the hilm is constant in every genus, and also sometimes in whole tribes, it is rery im-
portant in identification, and emables us to recognize the kind of attachment of the ovulum to the carpel eveu in the fruit. A punctiform or only short oblong hilum at the base of the fruit indicates a narrow, and an elongated linear hilum an extended, attachment. If there is a furrow in the fruit, then the hilum is always to be looked for in this, and moreoser invariably on the side of the palea, which must first be shaved off in those fruits where the pericarp is adherent to the bracts.

The embryo is usually small, seldom more than half as loug as the firuit, straight, rarely slightly hent (Oryzal, with the radicle tumed downwards. Its most striking portion is the scutellum (Sc in Fig. 6), which is regarded (although not undisputedly) as the cotyledou. It is a Hat but somewhat thick bocly, romudish to elongaterloval in circunference, lying close on its inner side to the alhmmen, with the plumule and radicle surromaded hy the coleorhiza situated in its somewhat shallow exterior. The plamule lies free upon the sontellum, hat below the plumule the axis of the embryo is mited with it; this is the point of insertion of the scutellum beyond which it projects downwards and outwards as far as the point of the coleorhiza (Fig. 6, E, H). This descenting portion of the scutellum is grown for a louger (Wheat) or shorter (Maize) distauce to the posterior part of the coleorhiza, and its edges are either free at both sides (Triti(chm, etc.), or they tum forward and grow so completely orer the colenthiza that they entirely mite in front or leave only a small cleft (Maize, $L$ in Fig. 6, $M$, Sorghmm). If this is the case, it is only in germination that the side portions are pushed hack (Fig. G, N) and the entire embryo becomes risible. The inside of the scutellum shows a peculiar kind of epidermis, the so-called cylinder epithelium, of palisade-formed, cylindrical cells with delicate walls. They are for the purpose of absorbing the dissolved amylaceous material of the albmmen. The seutellum also contains a fibro-vascular bundle, and this often has short branches. In germination it remains within the pericarp.

In many grasses there is in front of the embryo and

Fig i)-A, Jongitudinal section through the ovary of Barley (after Johannsen, "Das Endosperm der Gerste "); $m$, micropyle; $i_{1}$, $i_{2}$, outer and inner integuments: es, embryo-sac. $B$. opposite the scatellum a small scale-like appentage, the epiblest (ep in Fig. $6, E, O, P$ ). It is especially clear in Stipu (Fig. $6, O, P$ ), and yet better developed in Zizomin (where it is as long as the plumule), but is entirely lacking in many grasses (Rye, Maize, and Barley) ; generally it is merely a delicate formation consisting of parenchyma without fibro-vascular bundles, and its morphological nature is still doubtful. Yet the riew that it is a rudimentary second cotyledon is the most reasomable, for among other things this makes compreheusible the surprising position of the first leaf of the phumle just above (not opposite to) the scutellun. The plunule of the embryo consists of a rery short, often indistinct internode of the axis (epicotyl) and of two to four leaves, and according to the development of the former the plumule is sessile or petioled. The first leaf, the germ-sheath, surromuds the others like a closect tulbe, which hrealis through the gromul with its hard point at the time of germination, and opens at its apex after a time in order to allow the exit of the second leaf. It is colorless or pale green or frequently reddish. Many anthors consider it a part of the cotyledon, a riew which is certainly incorrect, for in many grasses (all Punicere, Andropogonere, Maydere, many F'estucerr and Hordere it is clearly separated from the scutellum at the time of germination hy a distinct internode (epicotyl) which is often much elongated (compare Fig. (i, $L$, st) . In others (Triticum, etc.) this epricotyl is very short or entirely lacking, so that the back of the sheath may even be grown to the scutellum.

The majority of grasses have only one radicle, ancl grow therefore with a primary root; in addition to which, especially from the epicotyl, new ronts snon arise which finally exceed the main root in growth. In sereral grasses, especially in the cereals, and also in Conir lachigme and others, the fommation of these secomelary roots is already laid before germination, uswally in the hypocotyl (the axis below the insertion of the scutellum); seldon, and only to a rudimentary degree, in the epicotrl (Zer, Fig. 6, $L, w_{1}$ ). The plane of these secondary roots
is parallel to that of the scutellum ; they can therefore be seen only in tangential (Fig. 6, $F$ ) aud uot in radial section (Fig. $f,(i)$ of the seed. In germination, each rootlet independently breaks through the coleorhiza, which surromuls each with a small sheath. Before the ronts hreak through, the elougating coleorhiza ruptures the

pericarp and sends numerous hairs from its epidermis, thus fastening the somewhat superficially placed seed to the gromul. The embryo is rich in oils and proteichs and even sugar, but contains no starch. The albumen consists of large, polygonal, parenchymatic cells which, with the exception of the outer layer, are rich in starch-
grains. Between these, which often fill nearly the entire space, finely gramular alluminons bodies are irregularly distributed or formed into a network of delicate plates, especially distinct in the peripheral layers. 'The inner cells show them but little, and are still richer in starchgrains. If the albmminoids so fill up the intervals between the starch-grains that the latter seem to be imbedded in cement, the albmen appears translucent and the fruit is called corneous ; but if the mion is less intimate, there remain numerous small air cavities, and the albumen is opaque and the fruit is mealy. Both conditions may occur in the same species or variety (Wheat), and they seem to be occasioned by differences in climate and soil. Corneons fruits are ustally richer in albuminoids than mealy ones of the same species.

Starch.-As to the form of the starch-grains, we mast distingrish between simple and compomad. The latter (Fig. 8, 6) are large and composed of many augular gramules, into which they often separate. Simple grains are gemerally present with them. The simple grains have central cavities and are either isodiametric aud polygonal (Fig. 7, A), or more rarely lens-shapert with rommed edges, in the latter case often distinctly lamellated and without central cavity. These lensshaped hodies are always mingled with many smaller ones, while the isodiametric grains are of tolerably miform size. These characters are constant within most genera, and even within entire tribes; they are therefore important from a systematic view, although they are uot without exception. At the time of germination the starch-grains become eaten through by the action of a lind of ferment, so as to be full of holes before they fall apart (Fig. 7. (1-g). The starch-grains of certain kinds of Rice (gluten rice), Sorghum (gluten sorghum), and of Millet, Panicum miliaceum, do not turn blue upon the addition of iodine, but red or reddish brown, and swell up rery quickly. According to A. Merer this is canserl hy their containing amylodextrin and dextrin. The ontermost layer and sometimes two or three layers of the albumen (Fig. 8, 5) contain no starch but small oil-
drops, and still finer proteid gramules are imbedded in the very delicate protoplasmic net. They are often called, but not properly, gluten cells : true glaten is not to be fonud in a dry kemel ; it is first formed from one of the albuminoids (Myosin) by the addition of water.

Fig. 8.-Avena sativa L. I, Cross-section of the entire fruit. II, A small piece of the peripheral portion, 1; 2, Pericarp; 3, Testa; 4, Remains of the nucellus; 5-7, Amylaceous tissue; 5, Gluten cells: 6 and $\boldsymbol{r}_{\text {, }}$ Cells of albumen containing compound starch-grains-at $i$ they are richer in albumen and poor in starch; 8, Fibrovascular bundle of the seed-coat. (From Harz, "Landwirtsch. Samenkunde.")
Frequently we understand by gluten the whole of the albuminoids, but these, as alrearly shown, are not found in the glutinous cells only. It has heen often asserted that bran and bran-bread (in which the ghtinons layer
is not removed) are very nourishing, but through later inrestigations this assertion has been bronght into question.

The so-called gluten layer is the outermost one formed in the embryo-sac ; ontside of it is to be seen a generally iudistinct, rarely very clear (Brach!poutium and Biomus) layer of cells, the remainder of the muclens of the seed; outside of this is the testa, which has arisen from the inner integument, the onter one having disappeared. Then follows the pericarp. (See above.)

Means of Distribution.-In all wild grasses certain parts of the spikelet or of the entire inflorescence fall off with the fruit. If the spikelet is many-flowered and every flower ripens its fruit, then its axis breaks into as many pieces as there are fruits, and every piece carries a floral glume aud palea. If the spikelet is one-flowerect, the axis of the spikelet may separate aloove the empty glume, so that the floral glume and the palea fall off with the fruit (Alyrostere) ; or it may divide helow the empty ghmme, and the spikelet fall off as a whole (Panicert, An(liopogonerr, etc.). If the spikelets form a spike or a raceme, it frequently happens that the axis of the latter divides, so that one spikelet falls oft with each joint (many Andropogonere and Horlere); short spikes (Triti"um ovatum Godr.) fall from the culm as a whole. All these arragements are necessary for the distribution of the seed; they are lacking (with two exceptions) in all cultivated cereals, but are present, on the contrary, in all mative races of the same species, so far as these are known. Since these arrangements are very disaltantageons for the complete gathering of the fruit, varieties whose axes are less or not at all artionated will be preferred in culture, and will be finally fixed by matural selection.

The bracts surrounding the fruit act as a more strongly developed pericarp; they potect the embryo, which is near the surface, from tor rapid wetting, and keep, the soluble contents form heing soaked out; and when it is once soaked through, they also protect it from (rying up) again. But they are especially important as means for distributing the fruit. They decrase the
specific gravity, and consequently the seed is letter adapted for transportation by the wind (very small fruits, like those of Agrostis and Erogrostis, which are light enough in themselres, usually fall eutirely out of the bracts), especially if the empty glumes accompany it and have a considerahle surface (Holcus), or generally the fruit-bracts are large in comparison with the fruit (Brizu), the whole haring the effect of a winged seecl. A still greater effect is produced when a large number of sterile glumes, or whole groups of sterile spilielets (Phalaris corvlescens Desif.), fall off with the fruit. The glumes or parts of the axis, if they hear long hairs, form a peculiar winged apparatus (Pliragmites, Arundo, Cultomagrost is, very many Andropogoners, especially those related to Succhurum: Melicu cilicute L., and Stipe pemmen L. (by its feathery awns), as well as many Aristicte species). Nany grasses are also adapted to distribution by the fur of animals, for either the hracts themselves (Tragus) or the awns (Horleum, Echinaria) are rery rough or have hooked bristles. In Streptochete the ripe fruit hangs from delicate spiral threads (the awns), which are fastened together at the end of the spike ; they are free below, and their stiff pointed bracts, bent outward, act like fish-hooks ly catching into the fur of :my animal that touches them in passing. The fleshy berries of many 'Bomblosere are evidently fitted for distribution by animals, which meither destroy nor digest the seeds. Not a few grass-fruits possess a powerful instrument in the surromnding bracts for fastening themselves into the gromad. First we find the base of such bracts prolonged into a pointed often prickly callus, which makes its penetration easy, and above the point are stiff hairs pointing upwards which make it difficult to draw out a bract that has once penetraterl the soil (Fig. 4t, cal). A rery strong bent awn, twisted like a rope below the bend, often acts as a motor. This awn is very hyeroscopic ; the coils unroll or unwind when damp, and when itry they return to their former condition; and every time this happens the point of the bract is rotated with lateral variations, especially when the upper half of the awn
has a support (a meighboring culn or merely an mueremess in the soil). This rotation and matation, together with the action of the bristles, soon canses the bract surrounding the fruit to bore deeply into the gromud (observed in several Stipu species, Heteropogon contortus R. de Sch., Avenu futur. L. and A. burderta Brot., several Aristidu species from Brazil and New Holland). If such boring fruits get into the wool of sheep, many kinds will in a short time hore through the skin into the intestines, where they canse fatal inflammation (oh)served in Stipa capillate L. in Panssia, S't. sperited Trin. in N. America, Aristide lyggrometricu. Br. in Queensland, Heteropogon contortus R. \& Sch. in New Caledonia). Fruit may also bury itself without the help of twisted awns ; in Triticum ovatum Godr. the spike falls off entire, and since it possesses a very pointed base and mumerous outwardpointing rough awns, where erer these find a hold they exert, by every movement of the wind, etc., a pressure upon the point, and this drives it into the gromd. (Herbarimm specimens loose between papers, creep backwards of themselves.) The entire inflorescence of Cormucopire (Fig. 46) falls off at the time of fruit, and the stem then hecomes curved and very pointed at the end. Whether this serves to bury it or to attach it to animals is mcertain.

The awns of Avenct steritis L. have a peculiar use. Two strongly awned fruit-bracts fall off fastened together; in moist surroundings the twisted awns begin to rotate their diverging upper halves, consequently they cross and press against each other until the bracts are forcibly separated, thus giving the fruit an impetus which throws it for some distance.

Finally, we will mention a peculiar method of distribution, viz., distribution by means of leafy spikelets. In many grasses, especially in high latitudes (south as well as north) and upon high monntains where the ripening of the fruit is often uncertain, it is not rave that entire spikelets or single flowers with floral glume and palea transform themselves into small-leaved shoots which are provided at the base with the begimmings of
roots. When these fall off from their axes they take root in the ground. In some grasses (Por stricta Lindb.) we know only this apogamic condition ; others are very seldom sexual (Deschempsict alpinu R. \& Sch., Festuce Fuegiunn Hook.), or the sexual stage is lacking in certain regions (Poct bulbose L.). Pou alpinu L. and Festucu ovina L. are always sexual in lower countries, but in high mountains in the north are frequently asexual. Such leafy panicles have a very curled appearance.

Geographical Distribution.-Grasses are found in all parts of the globe, and belong to the outposts of phenogamous vegetation in the polar regions, as well as to the limits of perpetual suow of high mountains. The greatest number of species is found in the tropical zone, but the number of individuals is greater in the temperate zones, where they are closely mited to form extended areas of turf that cover large meadows. The formation of meadows is dependent upon a uniform rainfall or continuons irrigation. Grasses also predominate in steppes and savamias, but here they grow in scattered sods or tufts and do not entirely cover the ground. The savauna grasses are characterized by the fact that they often reach above a man's head and are reed-like. The Bumbusere of the lowlands form an important part of tropical forests, especially in regions of the Monsoon. Upon South American mountains the bushy Bombusere form an entirely closed cover. Aside from the weedgrasses that have been generally distributed by commercial intercourse and colonization, there are several species that are cosmopolitan (for example, Heteropogon contortus R. \& Sch., and Phragmites communis Trin.), and still others that are native to both hemispheres (also to both tropics). Several species from the northern wooded regions (Deschumpsia flexuosa Trin., discolor R., utropurpurea Scheele, Festucu ovina L., rubra L., elatior L., Pora nemoralis L. and pratensis L.) are absent in the tropies, and appear again unchanged in the autarctic regions; others appear in isolated places between on high mountains of the tropics (Pllerm alpinum L.) ; still others (Alopecurus alpinus L., Trisetun subspicatum Beanv.) ap-
pear in varieties that may even be regarded as correspouding species. Not less than 90 genera are common to both continents; among these are many that are exchnsively tropical, and besides ten are single types. No one tribe is confined to one hemisphere, and no genus of momerons species to any one floral region. All this goes to prove that grasses are a family distributed very miformly, and that the separation of their tribes goes back to very ancient times. To be sure, the single tribes have varied under the influence of the later divisions into zones; while the Panicer and Andropogonere preponderate in the tropics, they are put in the background by the Festucere, Avenere, and Hordere in the temperate and frigid zones. 'The eastern North American forest region has preserved many more of them (and in general of tropic types) than has the Old World.

Fossil Grasses.-It camot be doubted that during the past geclogical ages, and especially in the tertiary period, grasses mast have been widespread and aboudantly dereloped. The numerons remains of grass-like leares are a proof of this, but any botanist who has made the matter a study will regard as a complete failure the efforts of some phyto-palroutologists to fix upon relations to living species from the crushed and compressed spikes and spikelets. The fragments described as Poucites Brongu., Armulinites Sap., Pseudophragmites Sap., Paleopy!rum Schmallh, may be entirely passed over ; but even others, whose forms point towards the living genera Oryze, Pomicmu, Uniolu, and consequently may lead to conclusions as to the reasons of the existing geographical distribution, are not sufficiently characterized for the determination of genera. There are still others which with good reasons may he referred to Armulo, Pliregmites, and perhaps to the Bambusere. (Engler.)

Relations.-The grasses form a very isolater family, showing close relationship only to the Cyperacea, but markenly differing in the structure of the froit and embryo (ontside position, shield-shaped cotyledon, ete.). The number of species is mencrain, since our knowlentge of them is mate obscure by a mass of symonyms. There
are probably about 3500 well-defined species. As in most isolated families, the sublivision of the grasses is very difficult and nowhere consists in single characters, but in a combination of them. No single tribe, no large genus numbering over 50 species, can be definitely characterized. The keys of analysis in Part II, especially the first, are therefore subject to many exceptions.

## PART II.

HEYS OF ANALYSIS AND DESCRIPTIONS OF TRIBES AND GENERA.

Note.-The numbers in parenthesis preceding the names of the genera refer to the corresponding genus numbers in Benthum df Hooker, Genera Plantarum.

## KEY TO THE TRIBES.

A. Spikelets one-, iarely two-flovered, lower flower when present imperfect; falling from the perlicel entire or together with certain joints of the ruchis at maturity. Ruchilla not produced beyond the flowers. Internodes between the different glumes or flowers not meusurable.
a. Hilum punctiform. Spikelets not flattened laterally, but usually somewhat dorsally compressed or else perfectly round.
$\alpha$. Flowering glumes and palea (the latter often wanting) hyaline. Empty glumes thick membranaceous to coriaceous or cartilaginous, the lowest the largest, with its edges embracing the others. Spikelets generally in racemes or spikes whose articulate axes break up at maturity.
I. f. and of spikelets in separate inflorescences or on different parts of the same inflorescence.
I. Maydeæ.
 arranged in the same inflorescence that a o stands near a ¢ . . . II. Andropogoneæ.
$\beta$. Flowering glume and palea membranaceous; empty glumes herbaceous, chartaceous or coriaceous, the first generally the largest; spikelets falling off singly or in groups from the continuous rachis. . . . . III. Zoysieæ.
$\gamma$. Flowering glume and palea membranaceous, empty glumes, herbaceous or chartaceous; the first empty glume smaller or narrower than the following ones. Spikelets falling off singly from the ultimate branches of the panicle.
IV. Tristegineæ:

万. Flowering glume and palea cartilaginous, coriaceous, or chartaceous. Empty glume more delicate, usually herbaceons, the first usually smaller. Spikelets falling off singly from the ultimate branches of the panicle or continuous (rarely articulate) rachis of a spike.

## V. Paniceæ.

b. Hilum linear, spikelets laterally compressed.
VI. Oryzeæ.
B. Spikelets 1-m.flowered, the 1-flowered frequently with the rachilla produced beyond the flowers, rachilla generally articulated above the empty glumes, so that these remain ufter the full of the fruiting glumes. When from two- to many-flourerd there always are distinct internorles between the flowers.
a. Culm herbaceous, annual ; leaf-blade sessile, not articulated with the sheath.
$\alpha$. Spikelets upon distinct (sometimes very short) perlicels, in panicles, spike-like pamicles, or racemes (without notches in the main axis).
I. Spikelets one-flowered:

1. Empty glumes four, palea one-nerved.
VII. Phalarideæ.
2. Empty glumes two (rarely none), palea two-nerved. . . . VIII. Agrostideæ. II. Spikelets $2-\infty$ flowered:
3. Flowering glume generally shorter than the empty ones; usually with a bent awn on the back, rarely awned from the point or awnless. When not awned there are two nearly opposite florets, and the rachilla is not produced beyond them. . . . . . . . . IX. Aveneæ.
4. Floral glume generally longer than the
empty ones, unawned or with a straight awn from the point (seldom below).
XI. Festuceæ.
$\beta$. Spikelets cowded in two close rows, forming a one-sided spike or raceme with a continuous axis.
X. Chlorideæ.
$\gamma$. Spikelets in two (rarely more) opposite rows forming an equilateral spike (very rarely unilateral). . . . . . . . . . XII. Hordeæ.
1). ('ulm (at least at the base) woody, leaf-hlade ofteu with it short, slemer petiole articulated with the sheath from which it finally separates.
XIII. Bambuseæ.

## T'ribe I.-Maydee.

The * spikelets occupying the upper portion of the inflorescence or of its clivisions, the of below. Grain ellipsoidal or roundish, unfurowed, with large embryo, and enclosed in a hard capsule formed by the glumes or part of the articulate rachis (Zeca excepterl), separating finally as a false fruit. Starch-grains simple, polyhertral. Culm tall, with pith; leaves broad, flat.

Remaiks.-Only the of spikelets are arranged in true spikes ; the o spikes, so called, of Maize, etc., are, like the spikes of Andropogonere, really racemes, since the spikelets corresponding to the primary branches of the axis of the spike are distinctly perlicellate. But since these pedicels bear secondary, sessile spikelets at their bases, and these apparently are borne on the main axis, the whole has the appearance of a spike. In Mraydere the term "spike" has been kept up also for the t racemes in order to avoid two different terms.
A. \& spilies numerons in terminul ponicles, of spilies in the axils of lernves sultended by large membranerceons bract.s at the base.
a. \& spikes of each leaf-axil free, articulated.

1. Euchlæna.
b. f spikes of each leaf-axil grown together into a continnous, compomul and much thickened axis (the "ear").
2. Zea.
B. \& spilies solitni!y ut the ends of the bronchlets, \& helow, 1-2, ench of them reeduced to a simgle spitielet which is
entirely enclused by the ouate or spherical, ivory-like sheath of the subtending bract. . . . . . . 7. Coix.
C. \& und of spilielets in the sume spike (at least in the luteirul spilies), the loucest empty glume of the of spilielets indurated.
a. The covering of the false firuit chiefly formed by the rachis, its opening in front closed by the narrow empty glume. . . . . . . 3. Tripsacum.
b. The covering of the false fruit chiefly formed hy the first empty glume, which is appresser to the narrow joint of the axis to which it is attached on the inner side.
$\alpha$. The terminal spikes $\hat{}$, the lateral mes amlrogrnons or $q$.
3. Polytoca.
$\beta$. Spikes all monœecious.
I. Several of spikelets above the of, the latter without membranaceons appendages.
4. Chionachne.
II. One of spikelet above every $\circ$, each of the latter provided with an open membranaceous appendage (the hardened outer glume). . . . . . . . 6. Sclerachne.
Note. - In the explanations of all the following tigures the letters are used as follows: A, entire inflorescence or part of the same; B, spikelet ; C, empty glumes (in order $\mathrm{C}_{1}, \mathrm{C}_{2}, \mathrm{C}_{3}, \mathrm{C}_{4}$ ) ; D, Howering glume ; E, palea ; F, tlower ; G, lodicules ; J, pistil ; K, fruit or grain. Special letters are explained in the descriptions.
5. (37) Euchlæna Schrad. (Rernce Brign.). Two さ spikelets to each joint of the rachis (one sessile, the other perlicellate), both two-flowered with membranacenns glumes; of in two-ranked spikes (apparently onerankerl). These spikes are fasciculate in the leaf-axils; the joints of the axis to which they belong are trapezoils, so that as they fall off, the obliquity of the upper smrface of one alternates in direction with that above or helow it. The elges of the cavity embrace the first cartilaginous empty glume, forming with it at maturity a smooth cartilaginous capsule or false fruit. Styles prolonged far beyond the leaf at the base of the spikelet, and two-cleft at the end. Tall ammuals with rery hroad leaves.

Only one species (E. Me.cicmu Schrat.) (Fig. 9) with

Fig. 9.-Euchlonu Mexicana Schrad. R. Joint of the rachis. St, Stirma. \%. Diagram. $A$ ㅇ, Single spike at the left; at the right, a tuft of the same surrounded by the sheath. (After Bot. Mag., plate 6414.) varieties (e.g., E. luxuriuns in Mexico, "Teosinte"). Stems 2-7m. high, very leafy, and valuable for fodiler in warm comentries; rarely blossoms in Europe, eren in the south. [Teosinte is cultivated in the Southern States for green fodder. It rarely blooms, and matures its seeds only in southern Florida.]
2. (38) Zea L. (Mays Gairtn.). Habit, foliage, o inflorescence, arrangement of the $q$ spikes in the leaf-axils with membramaceous basal bracts and the long projecting styles, as in the preceding genus, but the of spikes (originally by monstrons or teratological development?) are grown together into a spongy, continuous, club-shaped body (the "cob") upon which the 4-11 double rows (each sessile upon a low longitudinal elevation that is limited by a long shallow furrow on each side) eorrespond to a single spike of Euchloma. (train developed at the expense of the other parts, projecting beyond the thin bracts, which rarely become coriaceous and enclose it.

One species (Zert Mrays L.), Maize (Fig. 10), known only in its cultivated state, but originating at all erents in tropical America, apparently greatly changed ly coul-

Fig. 10.-Zea Mays L. (Grosser parts after Maout and Decaisne, details after Nees, Gen. I., 3. 4.)
ture. "Husk Maize" (see below) may approach the uat tive form in its glumes, the occasional division into more or less separated spikes, and an indication of articulations in the inflorescence.

The present condition, perhaps an anomaly obtained hy colture, is lacking in every means of distribution, and is therefore scarcely typical. The cultivation of Maize has not ouly extended into nearly all tropical and sub)-tropical countries, but has also penetrated into temperate regions (in Europe and North America, as a cereal, as far as $48^{\circ}$, and as a fodder plant still farther north), and around Lake Titicaca at 3900 meter's abore sea level. Culm 1-5 m . high, 1-6 cm. thick; leaves broad with modulating margins and gently drooping ends.

About sixty varieties are known, differing from one another in form, color, and size of fruit. The following are the most important:
a) Commom Duize. Ear 8-24 cm. long; kernel medium size, compressed from the back, rounded at the point, generally yellow ; rarely white, red, violet, black, blue, or variegated in the same ear.
i) Pearl Matize, very small, slender; kernels scarcely 6 mm . long, romal above, vitreons, very shiny like glassy beads.
c) Horse-tooth Marize. Kemels large, strongly compressed from the back, sides Hat, base dimple dented or creased. A very tall variety found especially in North America.

1) Sugar Mraze. Kernels much wrinkled, vitreons, appearing like gum arabic when broken, containing, instead of starch-grains, a soluble modification of starch, together with a little finely gramular starch. Cultivated in North America.
e) C'uzen Muize. Kernels 2.5 cm . in length aud 1.8 cm. in brealth, much compressed, tapering toward the base.
f) Husk Muize, with herbaceons, ovate, pointed emptr glumes entirely covering the kernels. If the ovary of yellow maize be fertilized with the pollen of a black
fruited variety, the resulting grain will be yellow with grayish-black flecks.

Uses.-The very nourishing meal is sometimes made into mush ("Polenta") by boiling, but its exclusive use gives rise to a skin disease ; it is also made into cakes ("Tortillas"), and sometimes mixed with wheat flour, or wheat and rye, to make bread ("Brown bread " of New England). The umripe ears are roasted or pickled in vinegar as a regetable; from the fruit the natives of South America prepare an alcoholic drink ("Chica"), another ("Pulque de Mahiz") is made in Mexico by the fermentation of the very sweet sap that is pressed out of the stem. In North America efforts have been made to make sugar from this juice. The boiled fruit makes an excellent food for swine and poultry, aud the entire plant, even the straw, is an excellent fodder for cattle. The husks are used for making paper as well as for hats, matting, and for filling beds, etc. The large variety horse-tooth maize) as well as that with striped leaves is used for lawn decorations in ornamental gardening.

Maize was imported into Europe soon after the discovery of America, at about the same time that Northern Europe received Buckwheat from Central Asia aud Russia. In view of the wide distribution it had attained when America was discovered, and the manner of its cultivation, its culture in this country must be rery ancient, thongh older discoveries are wanting, since the finding of maize-keruels in the renowned graverard of Ankon in Lima is not reliable, for determining its antiquity, for those graves were evidently used after as well as before the discovery of America.
3. (36) Tripsacum L. One to several upright terminal spikes, hesides those in the leaf axils. The f spikelets in pairs at each joint of the axis, two-flowered; the of single, one-Howered ; styles comnate near the base, stigmas long. Capsule or false fruit as in Euchlremr, hut separating less obliquely; at each side of the base of the empty glomes (as in Euchlon(a) there is a cavity for
the protruding radicle in germination. Tall peremnial grasses with rather broad leaves.

Species two or three, in sub-tropical America north of the Equator. Tr. ductyloides L. ("Gama grass") exteuds

Fig. 11.-Tripsacum dactyloides L. R, Joint of the rachis. (After Asa Gray, "Man.," plate 14.)

Fig. 12.-Coix Lacryma L. (After Mart. and Eichl., "Fl. bras.," II. II. plate 10.)
as far north as Illinois and Comnecticut, growing in wet places, and is used for fodder and also as an ornamental plant. (Fig. 11.)
4. (33) Polytoca Brown. (Cyuthorachis Nees.) Terminal panicle cousisting of from three to many \& spikes. Tas-
cicles of spikes in the axils of the leaves composed of $t$ spikelets abore and of helow; the latter with rather long sterile ghmes that are cartilaginons below and chartaceons above, completely enclosing the narrow joints of the rachis.

Species three, in the East Inclies, one (P. mucrophiyllı Benth.) in Louisiade Archipelago.
5. (34) Chionachne Brown. Culm much brancheu, branches terminated hy spikes that are subtended by a sheathing leaf. Spikes with 1-5) of and many (usually in pairs) を spikelets. Similar to Coix (see below), but the fruit capsule is formed loy the first empty glume.

Species three, in the East Turlies, Malayan Archipelago to Australia.
6. (35) Sclerachne Brown. Like the preceding, lut the spikes, which are half enclosed in the leaf-sheath, hare only one \& spikelet, and the of spikelet has an appendage upon the first empty glume. Species one ( $S$. punctata Brown) in Java.
7. (32) Coix L. (Lithergiostis (türtu.). Culm brancherl repeatedly, branches ending in one or two short, imorrlike, nearly globose capsules with an orifice at the top, and suromuling the of inflorescences, each of which contains one fertile and 1-2 sterile (often reduced to a pedicel) spikelets ; the ? inflorescence projects out of the orifices of the capsules, and is composed of spikelets in pairs. The capsule is formed by the sheath of the leaf at the hase of the of inflorescence, and often shows a rudimentary blade. Glumes of the of spikelets delicate ; style long, stigma short, hairy.

Species 3-4, in India aud China, and from there ( $C$ : Lucrymo L., Tear-grass ["Job's Tears"], Fig. 12) spread throughout the tropical zone; cultivated in China because the fruit is believed valuable as a diuretic and antiphthisis. In Catholic countries the fruit capsule is used for rosaries.

## T'ribe II.-Andropogonex.

Spikelets in spike-like racemes (cf. remarks on Maydece), two (rarely only one) at each joint of the usually
articulate rachis, one sessile and one pedicellate, often apparently three at the teminal joint. Laceme sometimes reduced to the termimal joint. Spikelets generally one-flowered with three empty ghmes, rarely a flowering glume with a ${ }^{t}$. Hower instead of the third empty glume ; first empty glume always more indurated than the flowering ghme, the latter often hyaline, usually bearing a hent or twisted awn. Palea msinally shorter than its glume, sometimes 0. Stamens three, rarely two or one. Style free, stigma phomose. Grain mufurowed, embryo nearly half as large as the fruit. Starch-grains simple, polyhedral to romulish. Mainly natives of elevated plains within the tropics, forming an important part of the grasses of the savamas.
A. Spikelets homogrmous, $\begin{gathered}\text {; joints of the ruchis not much }\end{gathered}$ thickened, nor excruvated for the reception of the spikelet. (Saccharere.)
a. Axis of racemes continuous.
$\alpha$. Spikelets solitary.
I. Spikelets on very short pedicels, disposed in one to several slender unilateral racemes.
8. Dimeria.
II. Spikelets pedicellate, forming a narrow, symmetrical, and much-branched panicle.
36. Cleistachne.
$\beta$. Spikelets in pairs, ravely in threes, mpon each joint of the rachis.
I. Racemes in a narrow spike-like panicle, spikelets awnless.
9. Imperata.
II. Racemes in broad often fan-shaped panicles, spikelets usually awned.
10. Miscanthus.
b. Axis of racemes articulate.
$\alpha$. Racemes solitary, terminal.
I. Spikelets in pairs at each joint of the rachis. 16. Pogonatherum.
II. Spikelets in threes at each joint of the axis.
15. Polytrias.
B. Racemes two to many, digitate or approximate on a shortened main axis.
I. Spikelets one-, rarely two-flowered ; when
two-flowered the first empty glume has a median longitudinal furrow. . 13. Pollinia.
II. Spikelets two-flowered, first empty glume without a longitudinal furrow.
25. Ischæmum (in part).
$\gamma$. Racemes in a much-branched panicle upon an elongated main axis, the lateral racemes sessile.
I. Spikelets awned. . . . . 12. Erianthus.
II. Spikelets unawned. . . . 11. Saccharum.
$\delta$. Racemes (usually short) in brauched pauicles with elongated main axis, the lateral racemes pedicellate.
B. Spikelets heterogamous or rarely homogamous, the joints of the axis of the raceme (false spike) appressed or grown to the pedicels of the primury spikelets, forming together with the perticels a hollow or excavation for the reception of the secondary spilielets: fertile glumes aluays raviless. (Rottboelliew.)
a. Joints of the rachis and pedicels complanate, not pressing against each other, but opposite ; the of spikelets sessile upou each joint of the axis and their posterior sides pressed against each other, embracing only by the edges. . 17. Ratzeburgia.
b. Joints of rachis and pedicels thick, appressed or grown together, the $\nleftarrow$ spikelets single upon each joint (very rarely in twos), entirely enclosed in front.
$\alpha$. First empty glume naked, awnless (at most only the terminal spikelet caudate).
I. The first empty glume flat or simply convex.
18. Rottbœllia.
II. First empty glume globose, with an opening upon the inner side which is closed by the joint of the rachis. . . 19. Manisuris.
$\beta$. The first sterile glume of all or of only the pedicelled spikelets awned or caudate.
I. Racemes simple or again disposed in racemes (compound).

1. Spikelets, both sessile and pedicellate (the latter sometimes apparently re-
duced to a pedicel) with $1-2$ short awns. . . . . . . 20. Rhytachne.
2. Sessile spikelets awnless, the perlicellate with long awns. . . . 21. Urelytrum.
II. Racemes digitate; the first glumes of all the spikelets long candate-pointed. 22. Vossia.
C. Spikelets heterogamous, the sessile of (irrely if), the perticellute さ, empty or uenting, very rovely all $\wp$ or all pedicellate. Joints of raceme not strongly thickened, nor with excavations for the reception of the spikelets. (Thelepogon excepted.)
a. Sessile spikelets two-flowered (Ischremere).
$\alpha$. Racemes reduced to the terminal joint with three spikelets, and enclosed by a sheathing leaf or bract.
3. Apluda.
$\beta$. Racemes with many joints.
I. Pedicellate spikelets developerl, flowerbearing.
$1^{\circ}$. Sessile spikelets awnless, perlicellate awned; first empty glume threetoothed. . . . . 27. Lophopogon.
$2^{\circ}$. Sessile spikelets awned or with the flowering glume at least mucronatepointed; empty glumes not threetoothed. . . . . . 24. Ischæmum.
II. Perlicellate spikelets, very rudimentary, or reduced to the pedicel.
$1^{\circ}$. First sterile glume pectinate-fringed at least at the base; racemes solitary, spikelets awnless. . . 25. Eremochloa.
$2^{\circ}$. First empty glume not fringed ; racemes two, closely appressed to each other; spikelets usually awned. 26. Apocopis.
$3^{\circ}$. First empty glume not fringed, transversely wrinkled and tuberculate; racemes digitate; spikelets awned. 23. Thelepogon.
b. Sessile spikelets, one-flowered (Eurndropogomere). Flowering glume of the perlicellate spikelets awnless.
$\alpha$. Axis of racemes indistinctly articulate, not brittle ; spikelets all pedicellate.
4. Trachypogon.

乃. Axis of racemes distinctly articulate; spikelets both sessile and pedicellate.
I. First empty glume with a balsam-bearing line within the side keels. Racemes solitary ; spikelets awnless. 30. Elionurus.
II. First empty glume without balsam lines. Racemes when solitary almost always awned.

1. A false whorl of four or more staminate or empty spikelets at the base of each raceme. Racemes solitary, short, usually subtended by a sheathing leaf.

* False whorl composed of four $\hat{0}$, oneflowered or empty spikelets.
$\dagger$ ४̧ spikelets with a pointed callus, readily separating from the false whorl. . . . 33. Themeda. $\dagger \dagger \stackrel{\rightharpoonup}{\text { spikelets without a callus, falling }}$ off together with the false whorl. 35. Iseilema.

** False whorl composed of 6-9 |  |
| :---: | two-flowered spikelets.

34. Germainia.
35. No distinct false whorl of $\delta$ spikelets at the base of the racemes, or where an imperfect one occurs, the racemes in pairs, subtended by a leaf-sheath.

* Fertile glume awned from the back or base ; leaves cordate at base.

31. Arthraxon.
** Fertile glumes awned from the point or from a more or less deep cleft, or awnless; leaves not cordate at the base. . . . . . 32. Andropogon.

## 1. Sub-tribe Dimerieæ.

8. (82) Dimeria R. Brown. (Haplache Presl., Ditactylon Zoll., Psilostachys Steud., Pterygostachyum Nees). Spike-

Fig. 13.-Saccharum oficinarum L. (After Bentiey et Trimen, "Medicinal Plants.")

A

B

Fig. 13.-Continued.
lets one-flowered, linear, laterally compressed ; first empr ty glume keeled, flowering glumes awned. Stamens two. Species twelre, in East Indies, S. China, N. Australia.

## 2. Sub-tribe Sacchareæ.

9. (73) Imperata Cyr. Spikelets one-flowered, deusely clothed with long silky hairs. Empty glumes membranacenus, narrow, the two outer with long hairs. Flowering glume small. Stamens 1-2. Stigmas long, exserted from the point of the spikelet.

Species five, throughout the tropical and sub-tropical zones, also in warm temperate countries. I. orrudinacea Cyr. is cosmopolitan in its several varieties. It forms the principal grass of the Alang Alang fields. in the Malay Archipelago, and furnishes material for thatching roofs.
10. (74) Miscanthus Andersson. Distinguished from the preceding loy the broad panicle, three stamens, and the flowering glumes more or less bifid and usually awnel between the teeth or lobes. Tall, the ample panicles terminal and usually silky hairy, rarely maked.

Species six, in Southern and Eastern Asia to Amur. MI. Sinensis Anders. (Euldiou Japonica Trin.) with awned spikelets, is a farorite omamental grass, as also is the more rare MI. sacchrwifforus Hack. (Imperata succhariftor" Maxim.) with awnless spikelets, from Amur.
11. (75) Saccharum L. Panicles usually expanded, the branches (racemes) many-jointed. Spikelets slender, the
somewhat hardened first and second empty glumes with long hairs (especially on the callus). Third empty glume (often 0 ) as well as the flowering glume and short palea hyaline. Anthers three. Tall grasses, usually with narrow leaves; the small spikelets sumounded loy long silky hairs.

Species twelve, mostly in the tropics of the Old World, only three (forming Sec. II) in America.

Sec. I. Spikelets all $\underset{\sim}{ }$. Panicles expanderl, axis of racemes articulate. To this section belongs $S$. officiunrum L. (Sugar-cane) (Fig. 13), which has a culm 2-4 m . high, $2-5 \mathrm{~cm}$. thick, with very juicy pith; leaves long, 2-4 cm. broarl ; panicles $40-80 \mathrm{~cm}$. long, pyramidal, and the third empty glume wanting. Native country not known, probably from tropical East Asia, but now cultivated in all tropical countries, especially in South America, and also in South Spain. In many comentries, especially in the islands of the Pacific Ocean, it readily becomes spoutaneons, and when this is the case it blossoms. For culture varieties are chosen which have heen reprorlucen for centuries by cuttings, and consequently have become nearly incapable of blooming. To propagate sugar-cane it is sufficient to place a piece of the culm possessing buts at its nodes, in a hole or furrow in the ground, where it will root rapidly if sufficiently moist.

The different cultivated varieties are distinguished almost entirely by the color aud height of the culm. The expressed juice or sap yields 17 to 18 per cent saccharose (crystallizable sugar), and the uncrystallizahle molasses that remains is used for the manufacture of rum. In many countries the fresh culms are sold for chewing. At present the colonial sugar industry is somewhat on the decline, a condition to which the manufacture of beet-sugar and the attacks of certain insects ( Tortrix sacchariphage, Coccus succlurit) have contributed. S. spontaneum L. with narrower leaves and a developed thind empety glume is found from Sicily (where it is also cultivated as a hedge plant) through the tropics of the Old World, and is a component of the Alang Alang fields of Sunta Islands (Malayan Archipelago), and of the grassbars of the Upper Nile.

Sec. II. Sclerostachya. Like Sec. I., hut the axis of the raceme is continuous. Spikelets all perticellate. Species one, in Asia.

Sec. III. Eriochrysis (Beaur. as a genus). Perlicellate spikelets of, smaller; panicle compact, interrupted; axis articulate. Species four, in South America and Cape of Good Hope.

Sec. IV. Leptosaccharum. Spikelets single along the axis of the raceme. Rachis not articulate. Species one, in South America.
12. (76) Erianthus Michx. (Ripidium Triu.). Differs from Suchlarum only by the awned spikelets. Lieed-like, narrow-leaved grasses with the usually expanded panicles clothed with silky hairs.

Species seventeen, in the warmer countries of both hemispheres. One species ( $E$ : Ravennce Beauv.) extends as far north as upper Italy. Also cultivated for ornament. (Fig. 14.)
13. (78) Pollinia Trin. Racemes usually digitate, seldom arranged in panicles. First and second empty glumes chartaceous or membranaceous, the third hyaline. Flowering glumes awned from the point or from a notch. Awns twisted or geniculate, very rarely 0 .

Species thirty-two, in the tropical and sub-tropical regions of the Old World.

Sec. I. Eulalia (Kunth as a geuus). Spikelets clothed with silky hairs. Leaves nar-

Fig. 14- Frianthus Rarennce Beallr. (After Nress, Gen. Germ. I. 90. A, Branch of the panicle.) row-linear.

Sec. II. Leptatherum (Nees as a genus, Nemustuchys

Stemi, Mifrostegimm Nees). Spikelet. slightly hairy, asually only upon the callas, rarely upon the keel. Leaves lanceolate, much narrowed at the base.

1t. (77) Spodiopogon Trin. Liacemes with long perlicels, usually with only two to three pairs of spikelets; first empty glume keelless, strongly 5-()-nerved. Spikelets somewhat laterally compressed, awned from a deep notch in the flowering glume.

Species five, in Asia Minor, Hindostan, China, Amur, and Japan.
15. (77c) Polytrias Hack. A low, prostrate grass with shining, red-hrown, hairy racemes, each joint of the rachis bearing two sessile and one pedicellate spikelet. Flowering glumes with a terminal awn.

Species one ( $P$. prcemorsa Hack.), in Java.
16. (79) Pogonatherum Beauv. (Homoplitis Trius.). Spikelets rery small, the second empty glume and the flowering glume with long delicate awns. Anthers two. Delicate grasses.

Sprecies two, in the East Indies ; one ( $P$. saccharoidenm Beaur.) extends to Japan.

## 3. Sub-tribe Rottbœellieæ.

Joints of the rachis and the spikelets usually naked.
17. (86) Ratzeburgia Kunth. Racemes (false spikes) linear, flattenect. Joints of the rachis curved abose; first empty glume reticulately ribbed.

Species one ( $R$. pulcherrimu Kinth), on the river Trawaddi.
18. (84) Rottbœellia L. False spikes cylindrical or slightly compressel; first empty glume coriaceons, covering the excaration in the rachis-joint; spikelets awnless.

A polymorphons genus with the following sul)genera:

Sulb-genus I. Colorlachis (Brougn. as a genns, Stegosin Lour.). Racemes solitary and terminal mpon the calm and its branches, articulate aud joints reatily separating ; joints of the rachis hollow at the apex,
free, ravely grown to the perticels of the lateral spikelets; spikelets usually one-fiowered, the pedicellate and sessile ones alike, the former rarely rudimentary.

Species twenty, in the tropics of both hemispheres.

Sub-genus II. Ophiurus (Gärtu. as a genus). Resembling Sub-genus I, but the lateral spikelets are alsent or rudimentar'y, and their pedicels grown

Fig. 15.- Rotthrellia loricuta Trim. (After Mart. et Eichl., "Flora Bras," II, III.) to the rachis ; sessile spikelets one-flowered.

Species four, in the tropics of the Old Work. In O. Tepvis Benth. (Innesithere Kunth, Thyridostuchymm Neps) there are frequently sessile spikelets, in pairs, upon the lower portion of the false spike. Opliurus may be correctly considered as an independent genus.

Sub-genus III. Hemutherin (Brown as a genus). Resembling Sub-geuns I, but the false spikes are more (o)mpressed, uot imperfectly articulate, and joints of the rachis hollow at the apex. Lateral spikelets formed like the one-flowered sessile spikelets, their perlicels nsmally grown to the rachis-joints so that the spikelets appear to be in pairs.

Species three, in warm countries extending heyond the tropics as far as South Europe and Tasmania.

Sub-genus IV. Peltophorus Desv. (Ifmisuris L., not Sw.). Like Sub-genus III, but the two contiguous sessile spikelets are very mulike, the first sterile glume of one having a broad margin ("bordered on each side at the apex hy a membranous wing"-Bentham); joints of the axis easily separable, with two appressed cavities at the apex.

Species three, in India.
Sub-gemus V. Thyrsostacluys. False spikes in a bushy panicle. First empty glune of the sessile, one
flowered spikelets almost membranaceons, coriaceons only upon the edges.

Species one, in Khasya Mountains.
Sub-genns VI. Phucelurus (Griseb), as a genus). False spikes in simple racemes, sessile, rarely solitary. All spikelets alike, two-Howered.

Species three, in the Orient, Himalaya, and East Asia.
19. (87) Manisuris Sw. Sessile spikelets one-flowered, hollow-globose, pitterl extermally; perlicellate spikelets Hat, $\quad$, or empty, their pedicels grown to the rachis.

Species one (M. gramularis Sw.), with leaves cordate at the base. A weed in all tropical countries.
20. Rhytachne Desv. Axis of the false spike articulate, easily separahle at the joints whose ends are at right angles to the axis and without appendages. First empty glume of the sessile spikelets rugose and with one or two terminal points or tails. Pedicellate spikelets rudimentary, awned.

Sub-geuns I. Eurytuche. False spikes terminal and solitary.

Species two, in tropical Africa; one of them said to occur upon the Antilles.

Sub-genus II. Judinerr (Steud. as a genns). False spikes, several, in a simple raceme, perdicellate.

Species two, in tropical Africa.
21. Urelytrum Hack. Axis of the false spike articulate, easily breaking into joints whose euds are oblique and provided with an appendage at the upper eud. First empty glume of the sessile spikelets smooth, awnless.

Species two, in tropical Africa to Natal.
22. (89) Vossia Wall. d Griff. False spikes digitate, stout, compressed. Rachis-joints curverl, notched, not excavated. First empty glume of the sessile spikelets smooth, and like the pedicellate produced into a long straight point or awn 1.5 to 2 cm . long.

Species one ( $V^{\prime}$. procera Wall. de (triff.), a tall, aquatic grass, frequently floating. In western India, and in tropical Africa, where it occurs in the swampy lands of the Upper Nile, forming, in company with Succhurnm spom-
taneum L., the vast floating grass-bars which frequently make narigation impossible.

## 4. Sub-tribe Ischæmeæ.

23. (90) Thelepogon Roth (Rhinirche Hochst.). Racemes digitate. Rachis flexuose, joints notched. Finst empty glume tuberculate. Flowering glume strongly awned from the notch.

Species one (Th. elegrons Roth), in India and Alysssinia.
24. (91) Ischæmum L. (Fig. 16). Racemes two to many, digitate, rarely solitary. Spikelets loroat, the perlicellate like the sessile, but frequently mawnect,

Fig. 16.-Ischœmum Urvilleanum Kunth. (After Mart. et Eichl., "Flora Bras, " II, III, \%i.)
rarely ₹ or empty. First empty glume coriaceous or membranacenus, ohtuse, often two-toothed. Flowering glume awned from the apex or a notch. Mostly low grasses with rather broad leaves.

Species thirty-four, chiefly in Southern Asia and Australia, very few in America and Africa.

Sec. I. Meoschium (Beauv. as a genus, Colladoa Car., Ischemopogon Griseb.). Racemes two to many.

Sec. II. Sehima (Forsk. as a genus) (Hologromium Nees). Racemes solitary.
25. (89) Eremochloa Büse non Watson (Pectinuria Benth. as a section). Racemes solitary, densely flowered, muilateral. Spikelets broad, awnless. Delicate, ornamental grasses.

Species six, in East Indies.
2(6. (80) Apocopis Nees (Amblynchyrum Hochist. I. Racemes in pairs (often having the appearance of being siugle). Spikelets crowded, the lowest sessile, ${ }^{\dagger}$, awn-
 grasses.

Species three or fonr, in East India, Clinin, and the islands of the Malayan Archipelago.
27. Lophopogon Hack. Spikes in pairs, appressed togrether, clothed with shining, rusty-l)rown hairs ; spikelets. crowderd. (Characters in the key.) A low, delicate grass with narrow leaves.

Species one (L. tridentutns Hack.), in western Inclia.
28. (98) Apluda L. Fiacemes minute, enclosed in the sheathe, fascicled ; fascicles in false panicles interspersed with ummerous leaves. Callus of the sessile spikelets spherical, both the other spikelets (one $\pm$ and one rurtimentary) upon broad, tlat pedicels.
species one iA. vorin Hack., with many rarietips (spikelets awned or awnless), in East Indies, China, and Australia.

## 5 Sub-ThiBe Euandropogoneæ.

29. (92) Trachypogon Nees. The long, pedicellate spikelet of every pair with a long stont awn; the * spikelet subsessile, ambless. Racemes solitary or two or three together, often clothed with silky hairs.

Species one ( $T$. polymorphus Hack.), in tropical and subtronical America, Sonthern Africa, and Madagascar.
30. ( 83 ) Elionurus Humb) of Bompl. Axis of the solitary raceme obliquely articulate, rensely hairy. First empty glume bifich or two-loherl, fringed ; spikelets with a strong lakism-like odor when fresh or after soaking in water, and hurning the tongue when chewed. [Two species within the limits of the United States, viz., $E$.
 biculmis Hack. (Wright, No. 2106).]

Species fifteen, mostly in tropical and smbtropical America, some in Africa, western India, and Australia. Savamat grasses, rejecterl by cattle. (The
strong lalsamic protucts in these grasses may protect them from being exterminated by grass-eating animals.)
31. (82) Arthraxon Bealv. (Plenoplitis Trin., Bathiot therom Nees, Lucren Kunth, Alectorictice Rich., Psiloporigon, Hochist., Lusiolytrum Steud.). Racemes msually digitate, delicate, often becoming true spikes hy the abortion of the $\pm$ spikelet together with its pecticel. Spikelets awned, very rarely awnless. Delicate grasses.

Species nine, in the tropics of the Old World; one extends to Japan, China, and Asia Minor.
32. (94) Andropogon L. Liacemes solitary or in pairs, digitate or panicled, oceasionally reduced to a few juints or to the terminal joint with three spikelets. Iatchis and callns of the first empty glume usually hairy. Spikelets usually narrow, the perlicellate $\uparrow$, emptry, in reducell to the pedicel, its flowering glume awnless, hat the first empty glume occasionally awned. Palea fiequently small or 0 .

A polymorphous genus, spread over all parts of the world in the tropical and temperate zones; the species prefer dry places, especially sammas. The ummerons sub-genera form two distinct series

Series A. Is shyygi. The sessile sipikelets of the lonest pairs in each raceme like those above as regards sex, form, and awns.

Sul)-genus I. Schizuchyrimm (Nees as a genus). Tiat cemes slemder, solitary, usmally smooth, terminal upom the culm or its bramches, the thickened joints of the rachis with a cup- or tooth-like appentage at the apex. Flowering glume often cleft nearly to the base, awned from between the divisions ; second empty glume awnless.
species twenty-seren, in the tropics, especially of America, and as far morth as New England (e.g., 1. scoparius Mich.).

Sul)-gewns II. Diectomis (Humb) \& Bompl. as a genus). Like Sub-genus I, but the spikelets laterally compressed, the second empty glume ammed, the flowering glume slightly notched at the point.

Species one, in tropical countries.
Sul-genus III. Hypogynium (Nees as a genus). Lia-
cemes solitary, terminal upon the branches and culm, subtended by sheathing leaves. Rachis slender, without appendages; flowering glume awned from the point or from a narrow slit, or awnless.

Species five, scattered throngh the tropics (A. spotheflorus Kunth from Paraguay to Cuba).

Sub-genns IV. Anuclelphiu(Hack. as a genus). Like the prececting, but only a part or none of the sessile, of spikelets are accompanied by of ones.

Species one, in tropical Western Africa.
Sub-genus V. Arthrolophis (Eulilastarom Steud. as a genus). Racemes mostly in pairs rarely digitate or

Fig. 1\%.-Andropogon Ischaemum L. After Nees, Gen. Germ. I. 92.) $B$, a pair of spikelets. panicled, the lateral ones sessile; joints of the rachis somewhat thickened, not translucent. Flowering glume usually bifid or two-toothed.

Species fifty, the majority American (A. Virginicus L. ["Broom Sedge"] and its allies, A. provincialis Lam., etc.).

Sub-genus VI. Amphitophis. Racemes digitate or panicled, all pedicellate. Rachis-joints and pedicels with a median, longitudinal, translucent line. Flowering glume pedicel-like, tapering into an awn.

Species fifteen, mostly of the Old World. A. Ischcemum L. (Fig. 17) of Central Europe and Asia, and A. saccharoides Sw. of America, belong here.

Sub-genus VII. Sorghum (Pers. as a genus, Blumenbachia Kül.). Racemes in panicles, frequently with few (sometimes only one) fertile spikelets. Rachisjoints without a translucent line, empty glume usually broad-lanceolate, finally indurated and shining.

Species thirteen, A. arundinaceus Scop. (A. Hotrapensis Sibth.) (Fig. 18) with a compound panicle, $2-5$ spikelets in each raceme, and fringed lodicules. Scattered in many varieties over the torrid and warm temperate countries. This is probably the original form of the cultivated Sorghmm or Black Millet races (A. Soryhum Brot.). In these the fruit and spikelets are usmally larger and rounder, and the rachis is not articulate. The most important are variety succheratus (Sorghom sacchuratum Pers.), Sugar Sorghum, panicles looser with drooping branches and red-brown spikelets; var. technicus, like the preceding, but the branches rery long, exceeding the shortened main axis; var. vulgavis (S. vilyave Pers.), with more compact panicles and light-colored obovate spikelets; var. niger, like the preceding, hut with black spikelets; var. cermm,s ( $S$. cermmom Host.), like vulgaris, but the culm is bent or recurved just helow the panicle; var. Dura, with more condensed panicles and deltoid spikelets, etc. The culture of Sorghmm probably had its origin in Africa, where "Durra," as it is called there, is now cultivated over the eutire continent, and has become the most important cereal. The natives also chew the stem, which contains sugar. It is also consideral) y cultivated in India and China. In Emrope it is raised less for breat than for mechanical purposes (especially the variety technicus); the panicles are made into the so-called "rice brooms," aud into brushes, etc. Italy, South France, and North America furnish the raw material in great quantity. In Germany, Sorghum, like Maize, is only occasionally maised for green fodder. In North America sugar is also made from the culms, and for this purpose the variety called Sugar Sorghum (S. succharatum) is used less than certain kinds of the variety vulgaris. In South Europe these industries may develop in the future. From the fruit the Caffirs make "Tictur," and the negroes "Merisn," alcoholic drinks. The fruiting glumes contain useful coloring matters.

Sub-gemus VIII. Ieficerin (Virey as a gemus). Ra-

Fic. 18. - Audropogom Songhem Brot. A. the oriminal form (A. Hrilripensis Sibth.). $B$, a cultivated form (var, vilg(eris); after Reichenb., Ic. 1503. $D, G$, and $K$, var. vulgaris, after Reichenb., VII. 465.
cemes rery many, in whorls mon slender pedicels, these are arranged above one another, forming a panicle.

Species two. A. squarrosus L., fil. (A. muricatus Retz., Anctlerum muricutum Beaur.). Spikelets small, narrow; empty glumes cartilaginous, beset with small spines. Swamp plants, callecl in India "Khushus" or "Bena," in the French colonies " Tetives." [Introdncert in Louisiana, where it has become spontaneons.] The rhizome is very aromatic. In India the whole plant is used in making the "Vessaries," or broad fan-screens, which when kept wet and placed in a current of air, cool and at the same time perfume the heated atmosphere of a room. When laid among clothing the rhizome keeps it free from insects. In European drug stores it is known as Rulix Auntheri or $R$. Vetiverire, a stimulant or antiseptic. It is also used in perfumery (Vitivert).

Sub)-geuus IX . Chrysopogon ('Trin. as a geuns ; Rherplis Lour.). Racemes whorled, perlicellate, usually reducent to one or two terminal joints. Spikelets somewhat laterally compressed.

Species twelve (A. Giyllus in S. Europe and Asia, etc.), with one exception (A. punciforus $=$ Sorglum punciflorum Chapm.) from the Old World.

Series B. Heterozygi. Sessile spikelet of the lowest pair or of several of the lower pairs (at least in one or two racemes) differs from the upper pairs in sex and awns, or is empty.

Sub-genus X. Dichenthinm (Willemet as a genus, $L_{t-}$ peocercis Trin.). Racemes usually three to many, digitate, all pedicellate or all sessile, not subteuded by a leafsheath. Flowering glume usually stalk-like.

Species ten, in the tropics of the Old World, two of them (A. piptatherus Hack., A. Aeesii Kunth) also in America.

Sub-gems XI. Cymbopogon (Spreng. as a gemus). Racemes in pairs, terminal upon the culm or its branches, one sessile, always with 1-2 basal homogamous pairs (of 2 ? spikelets), the other short perlicelled with or without homogamons pairs, hoth together subtended by a sheathing leaf, frequently arranged in a false panicle
interrupted by leaves. Flowering glume matually twotoothed, strongly awned. About forty species in the tropics of the Old World (very few in America). Predominating grasses of the savamas of tropical Africa. A. Nourdus L. (Fig. 19), in Ceylon and Hindostan, also

Fig. 19.-Andropogon Nardus L. (After Bentley et Trimen, "Medicinal Plants.")
cultivated, has very large pauicles, and is in all parts, especially the spikelets, rich in a rolatile oil, which when distilled is known in commerce as Citronella oil ; the closely related $A$. Schenonthus L., distinguished by a longitudinal furrow in the lower third of the first empty glume, is the source of Lemon-grass oil. Both are used as stimulants and auti-spasmodies for neuralgia and rheumatism, and are also employed in the adulteration of oil of roses. One variety of $A$. Schoenonthus is highly valued by the negroes for stopping hemorrhages. A. Tunige, Desf., from Nonth Africa to India, furnishes Hertue ichoenanthi or Junci ontorati, and A. Tworrencusa

Blane, is in use in Iudia as a medicine for cholera. From the related $A$. refructus Brown, the Tahiti ilsmulers prepare a cosmetic oil (" monoi "). Exothecu Ander'sson also belongs to this sub-genus.

Suh-genus XII. Heteropogon (Persoon as a genus). Racemes solitary and terminal upon the culm or its branches ; spikelets imbricaterl, the first to fifth pairs homogamons; awns large, and those of all the spikelets often entangled together ; of or \& spikelets with a pointerl callus.

Species five, in the tropics, one of which ( $A$. contortus L.) is cosmopolitan as far north as South Europe and North America. The fruiting glumes of these species easily bore into the skin and flesh of sheep by means of their pointed callus, and are thus a source of injury, especially in Australia. The awns may serve as hygrometers.
33. (97) Themeda Forsk. (Anthistiria L. fil., Androscepia Brongn., Heterelytrum Jungh., Perobachne Presl). The racemes are united into false panicles; they appear like a fascicle of $7-11$ spikelets. Occupying the middle of the racemes are $1-3$, long-awned, ¢ o spikelets; near these and in a false whorl at the base are the unawned of spikelets; the whole included in a foliaceous bract.

Species nine, in the warmer comntries of the Old World. Th. Forskalii Hack. (Anthistiria ciliata of authors, not of L. fil.) (Fig. 20) from Syria and Algeria to C'ape of Good Hope and Tasmania. This is the "Kangaroo

Fig. :0.-Themeda Forslialii Hack. (After Andersison, Munogr., Androp. pl. 3.) grass" of the Australian farmer, ofteu almost exclusively
(overing wide-extemting plains and monntain slopes in Australia and South Africa.
34. (97) Germainea Balansa do Poitrass. Infloreseence terminal, clustered, consisting of three central $f$, longawned, one-flowered spikelets, and of (i-9 * , awnless, two-flowered ones.

Species one ( (fx. crpituta Bal. d Poitr.), from Saigon to South China and the Khasiya Mts.
85. ( 97 §) Iseilema Anderss. Like Themerlı, hut more delicate. (For characters, see Key.)

Species three, in India, one in Australia. (I. Wrightiti Anderss. has a scent like bedbugs.)
36. (59) Cleistachne Benth. Resembling Sorghum in its habit and the hard empty ghme, hut without lateral ? spikelets or their perticels. Awns of the fertile glume terminal, stout.

Species two, one in the East Indies, one in tropical Africa.

## Tribe III.-Zoysiee.

Spikelets solitary or in groups, usually one-flowered, the flowering glume always awnless, membranaceons; the empty glumes of firmer texture and frequently awned. Rachis continuous. Otherwise as in Ampropogomere. A. Spikelets in gromps of fiom three to several at ench juint of the main axis ; each group falling off entire.
a. Spilies in pairs, articulate; spikelets 7-8 together. 37. Trachys.
b. Spikes or racemes solitary, continmons, terminating the culm or its branches.
a. Spikelet. 3-4 together, each gronp surroumederl by an indurated, pitcher-shaped pseudo-involucre formed by the first empty glume of each spikelet.
38. Anthephora.
B. (fromps of spikelets without an involucre.
I. Uppermost spikelet of each group sterile. Second empty glume coriaceous, with hooked spines on the back. . 41. Tragus.
II. Lowest spikelet of each group sterile, terminal one fertile, one-flowered with delicate glumes. . . . . 40. Ægopogon.

## III. Two outer spikelets $\hat{\text { o }}$, two-flowered ; one inner $\succ$, one-flowered. . . . 39. Hilaria.

B. Spikelets solitary, very rarely two upon each internoule of the rachis.
a. Empty glumes three, the third often having the function of the flowering glume of a $\hat{\delta}$ flower.
44. Neurachne.
b. Empty glumes two, these much longer than the flowering glume.
$\alpha$. Both empty glames with hooked spines upon the back, awnless. . . . . . . 42. Latipes. $\beta$. Both empty glumes with a fringed crest upon the back, awnless. . . . . 43. Lopholepis. $\gamma$. Both empty glumes smooth.
I. Empty glumes with long awns. 45. Perotis.
II. Empty glumes subulate, awnless.
46. Leptothrium.
c. Empty glume one.
$\alpha$. Empty glume coriaceous, acute, awnless.
47. Zoysia.
B. Empty glume with 3-5 awns. . 48. Schaffnera.
37. (64) Trachys Pers. (Trachyozus Reichb., Trachy.stachys Distr.). The outer spikelets of the cluster's : , the inmer $1-3 \nleftarrow$; the third glume very large, coriaceons, all the others much smaller.

Species one ( $T$. mucronata Pers.), on the sea shores of western India.
38. (63) Anthephora Schreb. (Fig. 21). Rachis strongly flexuose, spikelets fitting exactly into the curves in the joints. Pseudo-involucre below with 3-5 deep incisions; all spikelets $\succ$, awnless.

Species five ; one in tropical America, the others in tropical and southern Africa.
39. (60) Hilaria Kunth (Hexurthencr Presl, Pleuraphis Tori.). Empty glumes of the $\neq \underset{\sim}{\text { sple }}$ pikelets two-cleft, with ne to several awns, those of the spikelets very obtuse, short awned or awnless. Flowering glume awnless or mucronate-pointed.

Species five, from Central America to California and Texas.
40. (61) Egopogon. Humb, \& Bompl. (Hymenothecium Lag., S'chellingiu Steud.). Fascicles of spikelets secumd along i delicate axis, fimally pendent. Spikelets small, usually awned.

Species two, from Brazil to California.
41. (65) Tragus (Fig. 22). The 3-5) spikelets of each fascicle somewhat divergent. First empty glume minute, sometimes wanting; the second large, beset with hook-

Fig. 21. - Anthephora elegans Schreb. L, Involucre. After Mart. et Eichl., Fl. br. II. III. pl. 44.)

Fig. 22.-Tragus racemosus Hall. (After Nees, Gen. Germ., I. 23.)
like spines. Flowering glume and palea smaller and smooth.

Species (or varieties) two. Low, branching weeds, in all warm countries. [Introduced about Philadelphia, Mobile, etc.] The fruiting glume readily adheres to the wool and hair of animals.
42. (66) Latipes Kinnth. Spikelets curverl, very spiny, solitary or in pairs mone a very broad and flat pedicel,
finally bent downwards, and together with the pedicel they easily fall off.

Species one (L. Senegalensis Kunth), from Senegrambia to the East Indies (Scinde).
43. (67) Lopholepis Decne. (Hollbollia Wall. in Hook. Misc.). Spikelets very small, resembling a bird's head. First empty glume with a basal, knob-like protuberance (the head), theu suddenly bending outward and like the second, assuming the form of a beak. Delicate, ammal grasses.

Species one (L. ornithocephala Decne.), in Hindostan.
44. (68) Neurachne Brown. Spikes elougated or short and thick. Second empty glume largest and friuged within the edge. Peremuials with narrow and hard leaves.

Species three, in Australia.
45. (69) Perotis Ait. (X'ystidium Trin.). Spikelets narrow, delicate, very long-awned, stauding at right angles to the axis of the long, linear spikes. Leaves short and broad.

Species three, in the tropies of the Old World.
46. (70) Leptothrium Kunth. Empty glumes two, otherwise like the next.

Species one ( $L$. rigidum Kunth), in the warmer portions of America.
47. (71) Zoysia Willd. (Mutrella Pers., Osterdamia, Neck.). Spikes sleuder. Spikelets closely appresserl. Empty glume one, compressed, keeled, coriacenus, surrounding the flowering glume and palea. Creeping, maritime grasses with rigid and frequently sharp-pointed leaves.

Species 2-3, in Southern and Eastern Asia, on the Mascarene Isles, Australia, and New Zealand.
48. (72) Schaffnera Benth. Spikelets not in spikes, but disposed in clusters in the axils of the upper leafsheaths. Flowering glume with a single awn. A low, anomalous grass of very doubtful position.

Species one (Sch. Mexicana Benth.), in Mexico.

## - T'ribe IV.-Tristeginee.

Spikelets all $\underset{\sim}{\text { P }}, 1-2$-flowered, in panicled racemes; axis continuous. Empty glumes three, the thind sometimes having the function of a flowering glume of a ? Hower. Like the precerling tribe, this forms a tramsition between the Andropogomers and Panicere. All tropical.
A. Floncering glumes of the $\stackrel{+}{\text { s spikelets anned: a wons nsmally }}$ geniculute and twisted below.
49. Arundinella.
B. Flowering glume monless (fiequently, however, the 1-3̈ empty glumes are azned).
a. First empty glume very small, appressed to the one above.
50. Melinis.
b. First and second empty glumes rery small, resembling minute scales; spikelets in spikes.
55. Beckera.
c. First empty glume half as large as the secoud aud third, all a wnless.
$\alpha$. The long racemes of spikelets in distant whorls along a common axis. . . . 51. Phænosperma.
$\beta$. The short racemes of spikelets solitary along the main axis . . . . . . . 52. Triscenia.
d. First and second empty glume equal in length, half as long as the third and the flowering glume, all awnless; spikelets minute. . 54. Thysanolæna.
e. First empty glume subulate, awn-like, projecting beyond the others. . . . . . 53. Arthropogon. Note.-Compare Tricholena (Panicere).
49. (51) Arundinella Raddi (Goldbachia Trin., Acratherum Link, Thysanuchene Presl, Brandtia Kunth). (Fig. 23.) Spikelets perlicellate, usually in pairs upon the branches of the panicle, pedicels of mequal length. Firstempty glume shorter than the others, the secomel frequently awned, the third awnless, usually inclosing a of flower.

Species twentr-four, mostly in the tropical regions of the Old World, a few in South America [one in Mcxico].
50. (53) Melinis Beaur: (Tristegis Nees, Suntrlin

Schrk.). Spikelets very small, elliptical, maked; third glume usually awned; disposed in somewhat compact panicles.

Species one (II. minutiflora Beauv.), in Brazil, Ascension, Natal, Madagascar. In Brazil it is called "Capimmellado" on account of its glutinous properties. It is prized for fodder and is even cultivated.
51. (52) Phænosperma Munro. Pauicles large, branches in whorls; caryopsis projecting from the glumes half its length.

Species one (Ph. globosa), in China.
52. (54) Triscenia Griseb. A grass of doubtful relationship, on account of the small embryo, having nearly the same habit as Festuca ovinc. Panicles fewflowered. Spikelets one-flowered.

Species one ( $T$. ovina Gri- Fig. 23.-Arundinella Nepalensis seb.), in Cuba.
53. (55) Arthropogon Nees. Panicles loose. Empty glumes coriaceous, the second largest. One $\pm$ flower in the axil of the third gimme.

Species two ; one in Brazil, the other in Cuba.
54. (5®) Thysanolæna Nees (Myrinchera Zoll.). Panicles rery large, with innumerable minute spikelets in short racemes. Spikelets as in Panicum, but the flowering glume is delicate and fringed with hairs.

Species one (Th. acrifera Nees), "Tiger Grass," in tropical Asia-a troublesome weed among cultivated plants; $2-4 \mathrm{~m}$. in height.
5). ( 47 ) Beckera Fresen. Spikelets in ummerous spikes in the axils of the leaves. Third empty glume with a long straight awn, flowering glume awnless or
mucronate-pointed, three-nerved ; palea narrow, hy:aline, nerveless, two-toothed.
species three, in Abyssinia. Position of the genus doubtful.

## T'ribe V.--Panicez.

Spikelets one- (or occasionally two-) flowered, the second flower $\&$ (very rarely $\not \subset$ ), in the axil of the third glume; arranged in spikes, racemes, or panicles; axis usually continnous. Flowering glume and palea of the $\Varangle$ flower always firmer in texture than the empty glumes, unawned (empty glumes rarely awned). Fruit as in Andropogonere.
A. Spikelets all hermaphrodite.
a. Spikelets neither sunken in an excavation in the rachis nor subtended by a large leaf-sheath.
$\alpha$. Spikelets without any special covering consisting of bristles or spines (sterile branches).
I. Empty glume one. . . . . 56. Reimaria.
II. Empty glumes two, 字 flower single.
$1^{\circ}$. Lower empty glume with a swollen ring-like callus. . . . 60. Eriochloa.
$2^{\circ}$. Lower empty glume without a ring-like and swollen callus.

* Spikelets in one-sided racemes or spikes, these frequently in pairs or in panicles. . . . 57. Paspalum.
** Spikelets in panicles.
O All the spikelets alike, fertile, in terminal panicles.

58. Anthænantia.

O○ Spikelets of two kinds: first, the sterile, borne on a terminal panicle; second, the fertile, borne on short subterranean branches. . 59. Amphicarpum.
 61. Isachne.
IV. Empty glumes three, and $\begin{aligned} & \text { flower one, }\end{aligned}$ or a flowering glume with of flower instead of the third empty glume.
$1^{\circ}$. First and second empty glumes without a distinct callus, awnless.

* Flowering glumes without lateral appendages or pits at the base.

62. Panicum.
** Flowering glume with membranaceous appendages or pits at the base. . . . . . 63. Ichnanthus.
$2^{\circ}$. First empty glume very small, awnless, the second apparently distant from the first on account of a conical or pedicellike callus, and like the third (flowering glume of the of floret) more or less awned between the cleft apex.
63. Tricholæna.
$3^{\circ}$. First and second empty glumes awned.

* First empty glume without any distinct callus. . . . 65. Oplismenus. ** First empty glume with a pointed, pedicel-like callus. 66. Chætium.
$\beta$. Spikelets single or in pairs, subtended br an involucre consisting of from one to many bristles or spines (sterile branches) which are sometimes grown together.
I. Spikelets falling at maturity, bristles persistent.

67. Setaria.
II. Involucral bristles falling off with the spikelets at maturity (cultivated forms excepted). $1^{\circ}$. Bristles numerous, rigid, thickened at the base, frequently grown together.
68. Cenchrus.
$2^{\circ}$. Bristles usually numerous, apparently whorled, delicate, not thickened at the base, ofteu plumose. 69. Pennisetum.
$3^{\circ}$. Involucral bristles numerous, forming a paniculate, one-sided system of branchlets. . . . . 70. Plagiosetum.
$4^{\circ}$. Only one bristle below each spikelet.
69. Chamæraphis.

Note.-Compare Pennisetum, Sec. D.
b. Spikelets in small spikes, these surounded by large subtending bracts and united into a raceme.
72. Xerochloa.
c. Spikelets forming very short spikes which are sumken into carities of the one-sided, broad axis.
73. Stenotaphrum.
B. Plants monacions, diocions, or dichogemons, or the spikelets partly neuter.
a. Spikes very short, consisting of one $\wp$ and two to three upper, neutral spikelets crowded and mited into a one-sided spike with a leaf-like axis.

## 74. Phyllorachis.

b. One terminal, simple spike, consisting of one to two lower and four to six upper ? spikelets upon a broad (not leaf-like) axis. . . . 75. Thuarea.
c. Dicecious; of spikelets in heads' with spiny subtending bracts, ${ }^{\text {t }}$ in spikes which are mited into dense, globular heads. . . . . . . . 76. Spinifex.
d. Moncecions, spikelets scattered in panicles.
77. Olyra:
56. (1) Reimaria Flügge. Spikelets one-flowered, acmminate-pointed, in loose two-ranked, digitate spikes. Flowering glume and palea slightly indurated. Stamens two.

Species four, in tropical and sub-tropical America. [One species, R. oligostuclyy Mumro, in Florida.]
57. (2) Paspalum L. Spikelets one-flowererl, usually obtuse, in two- to four-ranked racemes or spikes, these two to many, digitate or disposed in panicles, seldom solitary. Flowering glume aud palea cartilaginous. Stamens three.

Species one hundred and sixty, in the tropics of both hemispheres, but most abmulant in America, forming an important component of the pampas and campos.

Sec. I. Eupusprolum. The lower empty glume and the flowering glume turned towards the rachis of the spike or raceme. $P$. dilatrtum (Fig. 24), with remote racemes, is a good forage plant, like many other species of
the genus. P.exile Kippist, with digitate spikes, aud spikelets 2 mm . long, is found in Sierra Leone, where it is cultivated ("Fundi" or "Fundungi"), the fruit being used for food; $P$ scrobiculatum L. (with racemes in pairs, and roundish spikelets having small pits at their bases) is used in India ("Koda") for food; the rhizome of $P$. distichum L. (with racemes in pairs, and oblong, pointed spikelets) is used in India as a medicine for inflammation of the gums and against conjunctivitis, and in the Argentine Republic for liver complaint; and $P$. notatum Flügge for gonorrhoe. The few species with only one empty glume form the sub-section Anachyris (Nees as a genus); those with the axis of the spikes leaf-like, form the sub-section Ceresia (Pers. as a genus).

Sec. II. Cubrerte (Lag. as a Fic. 24. - Paspahum dilatatumn genus). Like Sec. I, but the
rummers with scale--like leares. The open-flowered spikelets of the terminal panicle

Fig. 25. - Eriochloa grandiflora (Trin.) Hack. (Helopus grandiflome Trin.) (After Trin., Spec. Gram. nl. ars.) sterile.

Species two, in the Southeastern United States.
60. (5) Eriochloa Kunth. (Helopus Trin., Edipachne Link) (Fig. 25). Spikelets in racemes and these arranged again in simple or compound racemes. Spikelets, aside from the annular callus, as in Paspatum. Flowering glume mucronatepointed or very short-awned.

Species five, in the tropical and subtropical zones of both hemispheres.
61. (7) Isachne Brown. Spikelets in panicles, two-flowered, the fruiting glumes with the grain falling out of the persisteut empty ones.

Species about twenty, in the warmer countries of both hemispheres, especially of the Old World.
62. (8) Panicum L. Spikelets in spikes, racemes, or panicles, one- to two-flowered. First empty glume usually smaller than the second, and this as large as the third, which has the same structure but often encloses a flower. Flowering glume and palea indurated, awnless or very short-awned. Stamens three.

Species about three hmitrerl, in all warm and a few in temperate comntries. Ther form, with species of Prosprilum, excellent forage in the savamas and campos of South America.

Sec. I. Digitariu (Pers. as a genus, Symtherisma Walt.). Ratcemes (false spikes) simple, one-sided, digitate, rarely scattered. P. somgninnle I. (Fig. 26), "Blutfemich," is
a weed in gardens, but is cultivated in Bohemia upon saudy soils, where the fruit is used for mush and porridge; in the Southern United States, where it is known as Crab-grass, it is valued for fodder.

Sec. II. Trichuchne (Nees as a gemus, Acicarpa Raddi, Urochloa Kunth, Alloteropsis Presl, Holosetum Steud.,

Fig. 26.-Panicum sanguinale L. $A_{1}$, Part of a spike enlarged. A $1 / 2$ nat. size. (After Nees, Gen. Germ. I. 18.)

Fig. 2\%.-Panicum spectabile Nees. A $1 / 2$ nat. size. (After Mart. and Eichler, Fl. bras. II. II. pl. 22.)

Coridochloa Nees, Bluffia Nees). Racemes or panicles simple, usually with long silky hairs.

Sec. III. Thrasyre (Kunth as a genus, Tylothrasy" Döll.). Spikes with a broad axis, solitary. Flowering glume of the f flower frequently two-cleft.

Sec. IV. Echinolrena (Dess. as a genus). Spikes single, divergent (Genus No. 17 of B. \& H., Gen. Pl. III. p). 1107). Sec. V. Brachioria. Iuflorescence as in Posporlum, glumes awnless.

Sec. VI. Echinochlon (Beauv. as a genus). Spikelets in three-to four-rauked racemes, and these again in racemes or panicles ; second and thitd glumes more or less awned. $P$. C'rus-galli L., without lignles and with naked norles, is cosmopolitan, also cultivated for fodder ; one variety ( $P$. frumentaceum lioxb.) is coltivated in India for its fruit. $P$. spectubite Nees (Fig. 27), with a more distinct ligule and bristly-hairy nodes, is an extremely productive fodder-grass for tropical countries, and largely cultivated in Brazil.

Sec. VII. Hymenche (Beanv. as a genus). Spikelets small, in spike-like panicles. Flowering glume but slightly indurated.

Sec. VIII. Ptychophyllum. Spikelets in false spikes which are arranged in panicles; axis projecting beyoud the spikelets. Leaves plicate, elegant in appearance. $P$. plicutum Lam., from the tropies of the Old World, is a favorite ornamental grass in greenhouses.

Sec. IX. Eupanicum. Spikelets all pedicellate, in panicles, naked or with short hairs. $P$. Miliacenm L. (Millet) (Fig. 28) has loose trooping pauicles and ovate spikelets; first empty glume half as long as the second, flowering glume smooth and shining. Cultivated from prehistoric times. Native comntry manown, but probably the East Indies, where, and in China and Japan as well, it is yet much cultivated. It is raised to a considerable extent in South Russia and Rommania, but only here and there in other parts of Emrope. Several varieties are distinguished by the color of the fruit and the habit of the panicles. The fruit is mostly used for porritge ("Brei"). $P$. ultissimum Jacq. ( $P$. jumentorum Pers.), "Guinea grass," is $2-3 \mathrm{~m}$. high, spikes loose, upright, spikelets, lanceolate, fruiting glumes with fine transverse wrinkles. Native of tropical Africa. Cultivated as a fodder-grass, especially in America, on account of its rigorous and rapid growth. The rhizome of $P$. junceum Nees is used in the Argentine Republic as a substitute for soap for washing woollengoods. To this section belong (bleatremiu Griseb), Otuchyrinm Nees, Streptostuchys. Desr., all more or less anomalous species.
63. (9) Ichnanthus Beauv. (Nraviculuriu Raddi). Spikelets ovate or acute, short pedicellate on the brauches of the panicle, with one $\underset{\text { f and one }}{ }$ Hower. Leares broadlanceolate to ovate.

Species twenty, all in tropical America, one of them also in India.
64. (8\$) Tricholæna Schrad. (Rhynchelytrum Nees, Hochst., Monuchyion Parl.). Spikelets in loose panicles,

Fig. 28.-Panicum miliacerm L. (After Nees, Gen. Germ., I. 19.)
broad, somewhat laterally compressed, very hairy, especially on the callus of the second empty glume. The latter and the flowering glume of the f flower often thick-membranacenus ; flowering glume and palea much shorter, chartaceous, shining.

Species ten, in all parts of Africa: one of them extends to Sicily and western India, oue of which is endemic, two in Madagascar. Tr. rosed Nees, with reddish, silky hairs on the spikelets, awns shmet or wanting, from the C'ape
of Good Hope, is an elegantornamental grass, especially for dry bouquets.
(6). (10) Oplismenus Beatr. (Orthopogon Brown, Melaterosuche Steud.). Spikelets one-Howered, in small gromps or clusters along the brauches of the panicle, turned to one side; first and second empty glumes always, and the third frequently, awned. Broad-leaved, delicate grasses.

Species four, in the tropical and sub-tropical zone (one species in South Europe).
66. (11) Chætium Nees (Berchtoldia Presl). Spikelets lance-awl-shaped, pedicellate, in close panicles, oneHowered, all three empty glumes awned.

Species two; one in Mexico, one in Cuba and Brazil.
67. (12) Setaria Beauv. (Fig. 29). Spikelets 1-2 flowered, ovate, in a close, cylin-

F1g. 29.-Setaria glauca Beauv. $B+L$, Sp. with involucre of bristles. (After Nees, Gen, Germ., I. 22.) drical or bushy panicle. Glumes awnless, first empty glume short. Flowering glume and palea obtuse, finally hard and shining or transversely wrinkled. Involucral bristles usually projecting beyond the spikelets, rough.

About ten species, in all the warmer countries of the world; some as weeds in the temperate regions. S. glauca Beauv. (Fig. 29), with numerous bristles under each spikelet, and flowering glume with strong transverse wrinkles, is cosmopolitan. $S$. viridis Beauv., with 2-3 bristles under each spikelet, and flowering glume indistinctly transversewrinkled, is widespread, and is probably the original form of $S$. Itrtica Beauv., Hungarian grass, which is distinguished only by its larger panicles and thicker and larger spikelets which
do not fall off at maturity. The fruiting glume has, at its base, a smooth place enclosed by two slight longitudinal swellings and is not shining, a character which makes it easy to distinguish this species from the common Millets. Hungarian grass is extensively raised in Japan, China, some parts of the East Indies and TránsCaucasia, where it forms an important article of food ; in Europe its culture is less important, and it is mostly used for food for fowls.

The sixteen varieties may be divided into two main groups: large Millet, with loug, usually irregular, uodding false spikes, and "Mohar" (Hungarian), with short, regular, upright spikes. The culture of Setaria Itulica Beauv. has its origin in prehistoric times. As early as 2700 b.c., Hungarian grass formed one of the main cereals of the Chinese; it was sown in early spring by the princes of the royal house themselves, just as the emperor sowed rice with his own hand. Its culture extends back to an early date also in Egypt, and in the Lake Dwellings of the stone age it is found in such quantities that it must be regarded as the main breadsupply of the prehistoric peoples. Traces of its very ancient culture are also found in other places (Hungary, Upper Italy, etc.). Ixophorus Schlechtd. is a Setaria with only one bristle.
68. (13) Cenchrus L. (Fig. 30). Spikelets narrow, each one; or as many as two to three together, enclosed by an involucre. The involucres in a spike or raceme. First empty glume small, all awnless ; stamens three; styles mostly united below.

Species twelve, in the tropical and sub-tropical zones of both hemispheres, and in America also in the temperate zone. C. tribuloides L., bristles grown together into a coriaceous aud very spiny capsule. A troublesome weed in North America. The involucre adheres very strongly to the wool of sheep, from which it can scarcely be removed, and in consequence materially injures its value. It ought to be carefully ronted out in sheep districts. It is also very troublesome to workmeu who are
harefooted, like C'. myosuroides Humb. \& Kunth, in South America.
69. (14) Pennisetum Pers. Spikelets in racenes, spikes or false spikes, narrow or ovate, single or in groups of twos or threes, usually surrounded with many (rarely with ouly one) dissimilar bristles. First empty glume rery

Fig. 30.-A. Cenchrusechinatus L. (After Mart. and Eichler, Fl. bras., II. II. pl. 43.) $L$, Involıcre of $C$. tribuloides L . $L_{1}$, Cross-section of the same. $B$, Sp. of latter. (After A. Gray, Man. pl. 14.)

Fig. 31. - Pennisetum Prieurii Kunth. (After Kunth, Revis. pl. 119.)
small, flowering glume shorter than the second empty glume. Styles ofter united, projecting from the apex of the spikelet.

Species forty, mostly in tropical and sub-tropical Africa; one in Southeru Europe, and a few in America and Asia.

Sec. I. Pemisetum (Eriocheta Figari d De Notar. as a genus). Bristles numerous, all, or only the middle ones, bearded. P. villosum Brown, from Abyssinia, with broad spikes, is a favorite ornamental grass under the false name of $P$. longistylum (which belongs to Section III).

Sec. II. Penicillaria Willd. (as a geuns). Distinguished from the preceding section only by the artificial character (probably due to cultivation) of the permanent involucre. $P$. typhoideum Rich. (Penicill. spicata Willd.) " Pearl Millet" (Fig. 32), the original form and native country of which are unknown, has a culm 1-2 m. high, and fruiting panicles 8-20 cm . long, 2-4 cm. thick, and bearded. This is an important agricultural grass in Central Africa. The fruit is used for Mush ("Kuskus"). It is also grown in Arabia Felix and the East Indies. [Cultivated in the Southern United States for fodder.]

Sec. III. Gymnothrix Beaur. (Oxyonthe Steud.).

Fig. 3:.-Pennisetum typhoideum Rich. All involucral bristles naked. P. Tatifolium Spr. (Gym-
nothric lutifolice Schult.), with culns $1-1.5 \mathrm{~m}$. high, leaves broad-lanceolate, is an oruamental grass used for covering roofs of houses in the Argentine Republic, where it is native ; P. Juponicum Trin. (G'ymnoth. Juponicu), a lowgrowing species with linear leaves, is also an ormamental grass. Amphochuete Anderss. includes a species with spikes in panicles; Sericura Hasskarl, is a Malayan species with very long bristles.

Sec. IV. Beckeropsis (Fig. \& De Notar, as a gemns) has only one involucral bristle to each spikelet; spikes in panicles. Distinguished from Chumueraphis by the persistent pedicels of the spikelets.
70. (15) Plagiosetum Benth. One to two, narrow, acute spikelets within each involucrum.

Species one ( $P$. refructum Beuth.), in Australia.
71. (18) Chamæraphis Brown (Pucatheria Griseh.). Spikelets lanceolate, in simple or slightly brauched racemes, on short pedicels which fall off with the spikelets. First empty glume very short.

Species five ; four in tropical Asia and Australia, one in the West Indies and Brazil.
72. (20) Xerochloa Brown. Subtending bracts of the spikes husk-like, distichons; axis of the spike short, with a chaff-like continuation beyond the spikelets. Spikelets two-flowered ; flowering glume of $\not \underset{\mp}{ }$ flower very narrow.

Species three, in Australia.
73. (21) Stenotaphrum Trin. (Dicstemanthe Steud.). Spikelets $2-4$, forming a short, partial spike, embedded in the alternate notches of the broad rachis of a spikelike panicle ; axis of the spike with a chaff-like prolongation. Spikelets two-flowered, first empty glume small. Creeping grasses with compressed culms and flat, divergent leaves.

Species three or four, one of which, St. Americamm Schrank (Fig. 33), is widespread in the tropics and subtropical regions, and is useful for holding the sand on the banks of rivers. The rhizome is used in South America as a dimetic. The other species occur on the islands of the Indian and Pacific oceans.
74. (22) Phyllorachis Trimen. Each partial spike with one fertile spikelet, and 2-3 sterile ones reduced to single glumes ; axis prolonged. First empty glume minute, bristlelike, the third glume largest, with a palea in its axil. Besides the terminal leaf-like spikes there are solitary, longpedicelled spikelets in the axils of the leaves.

Species one (Ph. sagittata Trim.), with sagittate leaves, found at Coanza in Angola. Relationship doubtful.
75. (23) Thuarea Pers. (Microthuareia Thouars, Orinthocephalochloa Kurz). Spikes surrounded by a sheathing leaf; at maturity the dilated base of the axis envelops the 1-2 ¢ spikelets, and the rest of the axis, stripped of its Fic.33.-Stenotaphrum Americannm spikelets, forms a beak which schrank, (After Mart. and Eichler. bores into the ground. . A creeping maritime grass.

Species one ( $T h$. sarmentosa Pers.), from Ceylon to New Caledonia.
76. (24) Spinifex L. (Fig. 34). The \& spikes with projecting rachis, in dense heads with subtending bracts at the base; spikelets two-flowered; i spikelets oneflowered, with the pungent-pointed, subteuding bracts projecting far beyond them.

Species four ; three in Australia, the fourth from there to Cerlon aud Japan. At maturity the entire of head falls off and is carried away by the winds or floats on the sea, and finally presses itself into the sand by means of its bristles and falls in pieces. The species are an important agent in binding the drifting sands of the coasts. Leares usually with hard, rigid points. This
gemus should not he coufused with the "Spinifex" of Australian travellers (see Triodia).

Fig. 34.-Spinifex hirsutus Labillard. § plant above, \& below. (After Labill., Sert. PI. N. Holl. pl. 230, 231.)
77. (25) Olyra L. (Lithrehme Beaur., Strephium Schrat., Raddia Bertol.) (Fig. 35). All the spikelets one-flowered,
the ? upon the lower portion of the pazicle or in separate panicles, without empty glumes; flowering glume narrow and acuminate-pointed; of spikelets ovate ; empty glumes two, herbaceous, pointed or awned; flowering glume much shorter, cartilaginous. Lodicules three. Leaves broad, netted-veined, often with short petioles.

Species twenty, all, with the exception of one in Africa, from tropical America.

## T'ribe VI.-0ryzee.

Spikelets $̧$ or unisexual, one-flowered ; flowers apparently terminal and enclosed by a flowering glume and a palea which is usually one-nerved. Empty glumes two or none, very seldom numerous. Stamens frequently six. Stigmas more or less elongated, fruit usually with a small embryo

Fig. 35.-Olyra micrantha Humb. and Kunth. $A$ y/ natural size.
(After Kunth, Revis. Gram. pl. (Af
12.$)$ and long, livear hilum. Starch-grains compound.
A. Spikelets unisexual; plants monocious ; anthers six or more.
a. Spikelets in short, solitary spikes, terminal and axillary. . . . . . . . . 78. Hydrochloa.
b. Spikelets in panicles, or spikes arranged in panicles.
$\alpha$. Spikelets in pairs at each node of the paniclebranches ; one large, ㅇ, sessile, the other small, t, long-pedicelled.
I. Flowering glume linear-oblong.
79. Pharus.
II. Flowering glume inflated, globose, closed excepting a hole at the point.
80. Leptaspis.
$\beta$. Spikelets not in pairs at the norles of the branches.
I. Spikelets without empty glumes.
$1^{\circ}$. Spikelets linear. Embryo as long as the fruit. . . . . . . . 83. Zizania. $2^{\circ}$. \& spikelets ovate or elliptical. Embryo many times smaller than the fruit. * of and of spikelets in different panicles, rarely in the same, and then the o spikelets terminal on each branch.
81. Luziola.
** fo and of spikelets in the same panicle, the of terminal, the of at the base of each branch. 82. Zizaniopsis.
II. Spikelets with two very small or bristlelike empty glumes. . . 84. Potamophila.
B. Spikelets all $\succ$.
a. Spikelets arranged in panicles.
$\alpha$. Empty glumes two, short but distinct, awnless (two additional rudimentary empty glumes in Oryza).
I. Flowering glume and palea roundish in section (but slightly compressed).
85. Maltebrunia.
II. Flowering glume and palea much compressed laterally. . . . . . 86. Oryza.
$\beta$. Empty glumestwo, awned, exceeding or slightly shorter than the flowering glume.

* Empty glumes gradually tapering into awns.

58. Achlæna.
** Empty glumes awned from a hotch in the apex. . . . . . . . . 89. Reynaudia.
$\gamma$. Empty glumes wanting or present only as minute rudiments.
I. Flowering glume awnless. . 87. Leersia.
II. Flowering glume awned. . 90. Hygroryza.
b. Spikelets in a terminal, naked spike at whose apex the ends of the awns of all the spikelets are fastened together.
59. Streptochæta.
c. Spikelets in twos or threes in the axils of sheathlike subtending bracts.
$\alpha$. Only one subtending bract with 2-3 united spikelets terminating the culm. . 92. Lygeum.
$\beta$. Subtending bracts in two series with $2-3$ free spikelets in the axil of each. 91. Anomochloa.
60. (39) Hydrochloa Beaux. An aquatic grass with flat leaves, $3-5$ of spikelets in a terminal spike, a few of in each axillary spike, which scarcely exceeds its subtending sheath. Stigmas long.

Species one (H. Cerolinensis Beaus.), in the Southern United States.
79. (26) Pharos L. \& spikelets linear ; empty glumes two, short; Howering glume long, coriaceous, involute. Palea two-nerved. Spikes paniculate. Leaves broad, pedicellate; blade reversed. (See page 8.)

Species five, in tropical America.
80. (27) Leptaspis Brown. \& spikelets small, ferminat on the short branchlets; f spikelets $1-2$, sessile on the lower portions of same, large, globose, with two short empty glumes. Leaves as in Pharus.

Species five, in the tropics of the Old World.
81. (41) Luziola Juss. (Fig. 36). Spikelets awnless, ovate; flowering glume with many prominent nerves. Caryopsis with a thick, hard pericarp. Creeping, narrow-leaved, marsh or aquatic grasses.

Species six, from Brazil to Alalama.

Sec. I. Euluziola of and $\ddagger$ spikelets in separate panicles. Stamens usually more than six (6-18).

Sec. II. Caryochloa (Trine. as a genus). Arrozia Schrad. of and if spikelets in the same panicle. Sta-

Fig. 36.-Luziola Peruvian Joss. A ¿ spikelet. menus six.
82. (40) Zizaniopsis Doll \& Ascherson. Habit of Zizania. If spikelets terminating the branches of the panicle. Fruit a globose nut with a hard, shining, easily
separable pericarp. Embryo and hilum not risible on the outside. Stigmas united.

Species one, with two varieties-Z. miliucen Düll d Asch. [(Zizanice mitiucee Mx. ) in Brazil and the Souther'u United States.

8:3. (40) Zizania L. (Mychropyrum Link, Melimum Link). A reed-like grass with broad leaves and large panicles which are of and narrow, with the branches somewhat appressed above, and $\frac{1}{}$ and expanded helow. of spikelets almost subulate, awned, supported on thick pedicels. t awnless, lancerlate. Fruit a caryopsis 2 cm. long and 1 mm . thick, pericarp thin ; embryo very long, concealect in a furmow, with large epillast, plumule perlicellate.

Species one, Z. uquetion. L. (Z. putustris Link ant Hydropyrum esculentum Link), "Tuscarora rice" or " Inctiau rice," which grows mon the hanks of streams and lakes in North America and Northeastern Asia. The Indians ammally collect the fruit in quantities for food; they also sow the seed in order to provide for farther extension of the plants. Lately it has been sown in fish-ponds, for the frout, when it falls, is eagerly eaten by the fish.* The Asiatic form (Z. Tufifolion Turez.) is only a variety.
84. (42) Potamophila Brown. Spikelets lancenlate, awnless, in long pauicles whose lower brauches bear the of (with distinct staminodia in the flowers) and the upper the of or $\not \subset$ spikelets. Fruit spherical.

Species one ( $P$. parviffor, Brown), in Australia.
85. (42) Maltebrunia Kunth. Like the preceding, but with all the spikelets $\stackrel{\rightharpoonup}{\text {. }}$ Leaves broader, almost petiolate.

Species two, in Madagascar and Cape Colony.
86. (44) Oryza L. (Pudia Zolling \& Mor.). Spikelets elongaterl ; empty glumes of two simall seales or bristles, and mulerneath these two more minute rulimentary empty glumes. Flowering glume complicate and keeled, usually awned; palea narrow, one-nerved.

[^3]Stamens six ; fruit long, obtuse, closely enveloped by the fruiting glume, and compressed laterally with two lateral furrows ; embryo short, curved.

About six species, in the tropics of both hemispheres. O. sativa L., Rice, has contracted panicles and rough, prominently five-nerved flowering glumes. Wild in wet places in India and tropical Australia; one variety in Africa; naturalized in Brazil. Rice has been cultivated in China from the most ancient times (for over 2800 year's b.c.), in South Europe, where it was introduced by the Arabs, and in Egypt, since the middle ages (in Central Africa earlier?), in North America since 1700 A.D., and besides in Mexico, Brazil, and Paraguay. It needs stagnant water which readily breeds swampfever, and in Europe its culture in the vicinity of villages or hamlets is forbidden. Mountain- or Upland-rice, which requires only to be irrigated, is much less prized a for economic uses. Rice is used for food by more people than any other one grain. It is generally unsed in the form of soup or boiled Fig. 37.-Oryzasativa L. (after rice. "Arak" is made from it by

Fig. 3 .- Oryza sution L. (After fermentation; in Japan a light alcoholic drink, "Sake," is made from rice by means of an organic ferment. Gluten rice ("Klebreis"), whose grains stick fast together when cooked, forming a firmly united mass, and whose starch turns reddish hrown (see p. 26) insteat of blue with iodine, is used in Japan for paste and for making an elastic dough from which cakes are baked. In China a kind of sugar and a sweet drink are prepared from it. Rice-starch has lately become an article of trade, especially in England. Rice-brooms, rice-paper,
are not made from rice ; the first comes from Sorghnm, the second from Bronssonetia or Bambusa. About forty varieties are founded upon the color and size of the fruit and the absence or presence of awns.
87. (45) Leersia Swartz (Ifomalocenchrus Mieg, EhrJurtia Wigg., Blepherochlore Endl.). Distinguished from Oryza only by the aborted (indicated ly minute rudiments) empty glumes, awnless flowering glame, three, two, or one stamen (six only in L. hexendiou), aud the relatively smaller fruit.

Species five; swamp-grasses, one of which, L. oryzoides Sw., is found in the north temperate zone of both the Old World and New World; another, L. hexandra, throughout the entire tropical zone, and three in America only.
88. (46) Achlæna Griseb. Panicle widely expanderl. Spikelets large, linear-lanceolate, awned. First empty glume aristiform; flowering glume convolute. Stamen one. Caryopsis linear, with a very small embryo.

Species one ( $A$. piptostachya Gr.), in Cuba.
89. (56) Reynaudia Kunth. Spikelets long. Empty glumes subequal, two-lobed at the apex ; flowering glume short-awned below the point, slightly exceeding the empty glumes. Lodicules two; stamens two ; embryo small.

Species one (R.filiformis Kuntl), in Cuba. Leaves narrow ; branches of the panicle erect; spikelets small.
90. (43) Hygroryza Nees (Potcmochlou Griffith). Floating, aguatic grasses with broad, short leaves; the sheathis of the lower ones much inflated. Panicles umbellate, feiw-flowered.

Species one (H. aristata Nees), in the East Indies.
91. (30) Anomochloa Brongniart. An anomalous grass with long-petiolate leaves; the solitary apical spike with many large, sheathing bracts. Flowering glume memhranaceons, palea harder, closed and tubular below with a filiform appendage. A membranaceous fringed ring in place of the lodicules. Stamens four.

Species one (A. marantoideu Brongn.), in Brazil.
92. (28) Lygeum L. The united, very hairy flowering
glumes of the $2-3$ spikelets fiually form a hard capsule or false fruit. Palea linear, two-nerved, much exceeding the flowering glume. Styles elongated, stigmas short, feathery; stamens three; common subtending or sheathing bract of the spikelets lanceolate.

Species one, L. Spartum L. (Fig. 38), has a creeping rhizome and stiff, rush-like, convolute leaves. In rocky soil on the high plains of the countries bordering the Mediterranean, especially of Spain and Algeria. A part of the "Esparto" (see Stipa tenacissima) is furnished by this plant.
93. (29) Streptochæta Schrad. (Lepideilema Trin.). Distinguished from all other grasses by the spiral arrangement of its numerous (12) glumes, one of which bears a delicate, tendril-like, twisted awu.

Spikelets elongated, terete, acuminate. Stamens six, monadel- Fig. 3s-Lygerm. Spartum L. phous. Style one, stigmas three ; shreber. Beschr. d. Gris. leaves broad.

Species one ( $S$. spicrtr Schrad.), in Brazil. A genus of rery doubtful relationship, placed with the Oryzere on account of the character of its fruit. (For manner of dispersing its seed, see page 29.)

## Tribe VII.-Phalaridee.

All the spikelets fertile, one-flowered or with 1-2 flowers inserted below the apparently terminal one. Empty glumes four (the two inner ones rarely acting as flowering glumes for * flowers), unequal, the third and fourth occasionally very small, or one of them rudimentarr. Flowering glume and palea alike, laterally compressed, nerves one or none, awnless. Styles distinct; stigmas usually projecting from the point of the spike-
let ; caryopsis mufurrowed ; embryosmall ; starch-grains compound.
A. The thirel cund fourth (oir onty the fourth) empty glumes larger than the first and second.
a. Stamens six, rarely three. . . . 94. Ehrharta.
b. Stamens four or two.
$\alpha$. Panicles loose, third and fourth empty glumes equal, awned.
95. Microlæna.
$\beta$. Inflorescence a spike or spike-like panicle. Fourth glume longer than the third, awnless.

## 96. Tetrarrhena.

B. Third and fonith empty glumes smaller than or burely equalling the first and second.
a. Thirl and fourth glumes empty, reduced to small scales, awnless. . . . . . . . 97. Phalaris.
b. Third and fourth glumes empty, small, awned upon the back.
98. Anthcxanthum.
c. Third and fourth glumes, or at least the third, with a $₹$ flower, almost equalling the first and second, awnless or short-awned. . . . 99. Hierochloë.
94. (99) Ehrharta Thunb). (Trochera Rich.) (Fig. 39). Spikelets arrauged in panicles or simple racemes. First and second empty glumes short, the third and fourth frequently awnerl flowering glume slightly shorter, keeled, with a callus or tuft of hairs at the base.

Species twenty-four ; twenty in South Africa, two on Mascarene Isles, two in New Zealaud. Two have hecome naturalized in New Holland.
95. (100) Microlæna Brown (Diplax Hook.). First and secoud empty glumes very short, thitd and fourth longer than the flowering glume, all keeled; lodicules quite large ; stamens two or four. Iuflorescence panicnlate.

Species five, in Australia to New Zealand.
96. (101) Tetrarrhena Brown. Like the precerting, but the spikelets in a more simple, scarcely brauched spike. Fourth glume largest, indurated ; stimens four.

Species four, in Australia.
97. (102) Phalaris L. Inflorescence usmally a close spike-like, rarely interrupted panicle ; spikelets laterally compressed. First and second glumes boat-shaped,
usually with a membranaceons wing upon the keel. Flowering ghtue and palea hard, shining ; locticules distinct ; stamens three.

Species ten, mostly in Southern Europe; a few in Northern Europe and in America. Ph. concriensis, "C'anary grass" (Fig. 40), with strongly-winged keels on

Fig. 39. - Ehrharta Uvilleana Kunth. (After Kunth, Revis. Gram. pl. 6.)

Fig. 40.-Phalaris minor L. M,
Ph. canariensis L. (After Nees, Gen. Germ., I. 19.) the emptr glumes and the third and fourth emptry glumes half as long as the flowering glume, is cultivated in Southern Europe and in Germany. The gran is used for birdfood, and sometimes, in Southern Europe, as a cereal. From the flour, wearer's glue is prepared. Ph. armutinucen L., "reed-grass," with more open, interrupted panicles and wingless empty glumes, forming a distinct sectionDigraphis (Trin. as a genus, Beldingera Mey. d'Schreh.) grows upon river-hanks and is of some ralue for hay ; a rarietry with leares striped with white ("ribbou-grass") is cultivated for ormament.
98. (103) Anthoxanthum L. Spikelets in short, spikelike panicles, narrow; first and second empty glumes mequal, herbaceous; third and fourth clothed with brown hairs. Flowering

Fig. 41. - Anthoxanthum odoratum L. (After Nees, Gen. Gierm. 1). 10.) glume and palea short, membranaceous; lodicules none ; stamens two.

Species four, in Europe, one of them in Northern Asia, North America, and Australia. A. odoratum L. (Sweet Vernal-grass) (Fig. 41) is fragrant on account of its containing cumarin, and is often wrongly considered a valuable forageplant ; it forms a low turf which can scarcely be mowed, and its taste is umpleasant to cattle.
99. (104) Hierochloë Gmelin (Suvastanu Schrad., Dis(1rrenum Labill., Torresia Ruiz d Pav.). Inflorescence an open or close panicle. Spikelets shining, having one apparently terminal $\begin{gathered}\text { flower with two stamens, and 1-2 }\end{gathered}$ t flowers below, each with three stamens. Flowering glume of the male flower frequently awned. Glumes all membranaceons, those surromuling the fruit indurated. All contain cumarin.

Species thirteen, throughout the temperate and frigid zones, rarely in high mountains of the tropics. H. odorata Wahlb., Vanilla grass (Fig. 42), is very fragrant, but useless for forage, as it is disliked by most animals. [The long leaves of the sterile shoots are woven
 into mats and small boxes by Fig. 49.-Hierochloe odorata Wahlb. the North American Indians.] The five species with only one \& flower form the section Ataxia (Brown as a genus).

## 'Tribe VIII.-Agrostidee.

Spikelets usually all $\underset{\text {, one-flowered, rachilla some- }}{\text { son }}$ times prolonged beyond the palea. Empty glumes ofteu somewhat unequal, usually as long as or longer than the flowering glume, very rarely none; palea usually twonerved; grain not sulcate; embryo usually small; starch-grains compound.
A. Flowering glume indurated at maturity (at lenst firmer in texture than the empty glumes) and very closely enveloping the fruit. (Sub-tribe Stipere.)
a. Spikelets all $\underset{\text {, fertile. }}{ }$
$\alpha$. Rachilla not prolonged beyond the palea.
I. Flowering glume deeply three-cleft, each segment awned; palea two-awned.
100. Amphipogon.
II. Flowering glume entire, awned ; awn trificl or three-branched (lateral divisions often very short). . . . . . . 101. Aristida.
III. Flowering glume entire [two-toothed or bifid]; awn simple.
$1^{\circ}$. Lodicules usually three, flowering glume and palea finally very hard.

* Flowering glume narrow. Awn twisted, stout, persistent.

102. Stipa.
** Flowering glume broad, awn slender, falling off after flowering.
$\dagger$ Flowering glume elliptical or ovate, net gibbous at top ; awn terminal or but slightly eccentric ; embryo small.
103. Oryzopsis.
$\dagger \dagger$ Flowering glume obliquely obovate, gibbous at top; awn decidedly eccentric; embryo small.

- Palea membranaceous, without nerves or keel.

104. Nassella.

OO Palea coriaceous, twokeeled, with a deep furrow between the keels.
105. Piptochætium.
$2^{\circ}$. Lodicules two (anterior); awns slender, sometimes reduced to a mere point. Palea simply membranaceous, spikelets small. . . . 108. Muhlenbergia. (N.B. Compare Limnas.)
IV. Flowering glume awnless. . 106. Milium.

乃. Liachilla with a pedicel-like prolongation beyond the palea.
I. Both empty glumes much shorter than the flowering glume, the latter with a straight, terminal awn. . . . 109. Brachyelytrum.
II. Second empty glume one fourth shorter than flowering glume, the latter with a terminal, recurved awn.
110. Podophorus.
b. One $\varnothing$ and one (or sterile spikelet) in pairs on each branchlet of a spike-like panicle, these branchlets clecidnous at the time of fruiting. 111. Lycurus.
c. $\begin{gathered}\text { spikelets surrounded at the base with mumerons }\end{gathered}$ sterile (and a few ?) spikelets which are either reduced to bristles or delicate bracts.
112. Perieilema.
d. Spikelets dioceious, the of solitary upon long perlicels.
107. Aciachne.
B. Flowering glume usurlly higaline or membranaceons at maturity, at lenst more delicute than the empty glumes; grain loosely or not at all enclosed.
a. Stigmas sub)-phumse (their very short hairs springing from all sides), projecting from the apes of the nearly closed glumes.
$\alpha$. Spikelets in a heat which is sumounded by a bell-shaped involucre formed by the uppermost leaves.
113. Cornucopiæ.
$\beta$. Spikelets in a flattened (broader than long) head which is enclosed between two opposite inflated sheaths with thorm-like blarles. . 114. Crypsis.
$\gamma$. Spikelets in a close, often shortened false spike, the upper leaf not forming an involucre.
I. Spikelets readily falling off at maturity. 119. Alopecurus.
II. Empty glumes persistent; flowering glumes usually deciduous.
$1^{\circ}$. Flowering glume awned from below the bifid apex. . . . 118. Echinopogon.
$2^{\circ}$. Flowering glumes awnless.

* Flowering glume somewhat longer than the empty ones. . . 115. Heleochloa.
** Flowering glume somewhat shorter than the empty ones, the latter with winged keels. . . . . 116. Maillea.
*** Flowering glume much shorter than the wingless empty ones. 117. Phleum.
o. Spikelets in a delicate, simple spike.

120. Mibora.
$\epsilon$. Spikelets in a panicle consisting of small umbellike clusters; empty glumes none.

## 121. Coleanthus.

5. Spikelets in a short, narrow panicle; empty glumes short. . . . . . . . 122. Phippsia.
\%. Spikelets in a loose, broad panicle, empty glumes as long as the flowering glumes and falling off with them.
6. Limnas.
b. Stigmas distinctly plumose (branchlets distichous), projecting from the sides of the spikelets, rarely remaining enclosed within them.
$\alpha$. Grain not covered by the flowering glume and palea, usually with a looselyattached pericarp which opens readily at maturity. . 123. Sporobolus.
$\beta$. Grain covered by the flowering glume and palea, pericarp adherent.
$1^{\circ}$. The entire spikelets deciduous (together with the whole or a part of the pedicel) at maturity. The pedicel of the spikelet often being distinctly articulated even at the time of flowering.

* First empty glume long-a wned.

125. Chæturus.
** First and second empty glumes awned.
126. Polypogon.
*** Empty glumes awnless or only the second very short-awned.
$\dagger$ Flowering glumes awned from the very point or not at all.
127. Garnotia.
$\dagger \dagger$ Flowering glume awned below the toothed point. . . 128. Thurberia. [Cinne, No. 131, may be looked for here.]
$2^{\circ}$. Empty glames persistent upon the unarticulate perlicel of the spikelet.

* Palea one-nerved, with one keel; stamen one. . . . . . . 131. Cinna.
** Palea two-nerved, rarely wanting; stamens three.
$\dagger$ Empty glumes covered with loug plumose hairs. . . 144. Lagurus. $\dagger$ Empty glumes saccate at the base, many times longer than the flowering glumes.

134. Gastridium. $\dagger \dagger$ Empty glumes neither plumosehairy, nor saccate at the base.
O Flowering glume four-cleft, each division terminated by a fine straight awn besides a strong twisted awn upon the back.
135. Pentapogon.

O○ Flowering glumes two-cleft, the divisions awn-pointed, and between these an awn that is tortuous below. 142. Diplopogon.
$\bigcirc \bigcirc \bigcirc$ Flowering glumes with two fine lateral awns exceeding the length of the glume, and a delicate dorsal awñ. 141. Trisetaria.
2000 Flowering glume with a delicate awn, inserted below the point and many timeslonger than the glume. $\triangleleft$ Second empty glume larger than the first. . 139. Apera. $\triangleleft \triangleleft$ Empty glumes equal.
140. Dichelachne.

Flowering glumes different from those under $\bigcirc$ to $\bigcirc \bigcirc \bigcirc \bigcirc$.
$\triangleleft$ Callus, or prolongation of the rachilla, having a tuft of hairs at least one third as long as the flowering glume. X Spikelets all $\wp$.
$\square$ Flowering glume and palea thin-membranaceous.
136. Calamagrostis.

- F Flowering glume and palea chartaceous, panicle spike-like.

138. Ammophila.

Tロロ Flowering glume and palea chartaceous, panicles expanded.

138a. Calamovilfa. XX Spikelets unisexual.
137. Cinnagrostis.

Q $\triangleleft$ Callus naked or with a few very short hairs.
X Spikelets in a long, narrow, many-flowered panicle.
124. Epicampes.

XX Panicles pyramidal, oval, or short and spike-like.

- Empty glumes somewhat shorter than the flowering glumes, spikelets large.

130. Aretagrostis.
$\square \square$ Empty glumes longer than the flowering glumes.
§ Without a distinct prolongation of the rachilla beyond the palea. 132. Agrostis.
§§ With a distinct, bristle-like, naked prolongation of the rachilla.
131. Chætotropis.
§§s With a distinct prolongation of the rachilla in the form of a pencil of hairs. 135. Triplachne.

## Sub-tribe 1.-Stipeæ.

Fruiting glume more or lesis indurated, closely embracing the grain.
100. (119) Amphipogon Brown (Gamelytrum Nees). Tuflorescence capitate, or a dense spike-like panicle with numerous awns, even the palea having two long awns.

Species five, in Australia.

Fig. 43.-Aristidt corrulescens Desf. (Trin., Spec. Gram. pl. 313.) Pentacraspedon Steud. belongs here.
101. (108) Aristida L. Panicles usnally expanded. Empty glumes usually longer than the flowering ones, the latter with a pointed callus; palea shorter ; lodicules two.

Species about one hundred, in the warmer portions of both hemispheres, very few in the temperate parts of Europe and Asia, but numerous in North America.

Sec. I. Chretaria (Beauv. as a genus). Awns naked, not deciduous. A. crerulescens Desf. (Fig. 43), in South Europe and North Africa. A. hygrometrica in Queensland, is dangerous to sheep (see page 30). Streptachme Kunth (Oitrache Nees) has either no lateral awns or ouly very short ones.

Sec. II. Arthratherum (Beauv. as a genus). Awns naked, deciduous.

Sec. III. Stipugrostis (Nees as a gemus. Schistrchene, Fig. de De Notar.). Awns plumose, deciduons. Grasses of the high plains and deserts of Atrica and Western Asia.
102. (109) Stipa L. Panicles usually expanded, empty glumes narrow, oftell awned, longer than the flowering glumes, the latter usually with a hairy callus; awns geuiculate, usually twisted below the geniculation, finally deciduous.

Species about one hundred, distributed throughout the temperate and tropical zones, growing especially on elevated plateaus and savannas, and upon rocky soil. Leaves frequently filiform or stiff and rush-like.

St. pennata L., with long plumose awns, togethei with St. tirsa Stev, and the following species (viz., St. capillata), form the principal grasses of the Russian Steppes. St. pennata is also an ornamental grass for dry bouquets.

St. capillata L. (Fig. 44) has
 naked awns that are curved irreg- Fie. H.-Stipu capilluta L.. cmb, ularly back and forth towards the end. The finuting glmme with its pointed callus easily bores through the skin of sheep, reaches the intestines and causes death (especially in Russia), as does the "Porcupine grass" (St. spurter Trin.) of North America. Upon the prairies and especially upon the elevated plains of the West the mmerous species of Stipre form a comsiderable portion of the "bunch" grasses, and furnish much but rather coarse grazing for stock. St. tenacissimu L. (Macrochlore tenucissimer Kunth) is called "Esparto" in Spain and Helffe or Alffi in North Africa; it has comtracted panicles, two-cleft flowering glumes awned from
hetween the teeth, and very long, stiff, cylindrical leaves; it yields material from which shoes, mats, ropes, etc:, are woven, and from which paper is manufactured ; it is exported in bulk from Spain, Algiers, and Morocon, especially to Eugland. It is worthy of note that certain species of Stipuact upon cows, and more especially upens horses, as marcotics. This fact is established in regard to St. inehrions Hance, St. viriduln Trin., aud a species growing in Cashmere, probably St. Silhiricu Lam.

To the genus Stipu belong a large number of groups of species which may be regarded as poorly defined sertions, which have been distinguished by some as genera; viz, Mherochloa Kunth, Aristellu Bertol., Streptuchue Brown (Orthoraphium Nees), Jaraura Raiz \& Paron, Lusingrost is Link (Achuathernm Beanr.), and Ptilugrostis Griseb.

10:3. (110) Oryzopsis Michanx (Piptutherum Bealur, Trochue Trin. (in part), Ditepyrum Rafin.). Distinguisher from Stipu by its broader flowering glumes with their shorter, more slender and deciduous awns; lodicules often only two ; epiblast of the embryo short.

Species fifteen, in the northem temperate zones of both hemispheres. Eriocoma Nutt. (Fendleria Steud.) forms a section with two species, in western N. America, distinguished by the long and densely haired flowering glume.
104. (110 Nassella Dest. Palea short, membrana(cons, nerveless; epiblast projecting beyond the plumule.

Species eight, in Pern, Chili, and the Argentine liepublic.
105. (110 S Piptochætium Pres. Palea coriaceorns, its apex projecting beyoud the flowering glume ; epiblast large.

Speries fire, in extra-tropical South America.
106. (111) Milium I. ( Mitinrinm Mrench). Fruiting glames strongly indurated, shining as in Ponicum: ]maicles diffuse.

Species 5-6, in Europe and the temperate portions of Asia, one also in North America (M. effusum L.), a forest
grass with drooping leaves, the blates of which are reversed (see page 8).
107. (112) Aciachne Benth. A dwarf grass with closely two-ranked, short leaves and a single of spikelet terminating the culm. Fruiting glume with a long subulate point. क spikelets unknown.

Species one (A. pulvinat(r), in the Andes of the tropics. 108. (113) Muhlenbergia Schreb. (Fig. 45). Panicles

Fig. 45.-Muhlenbergia diffusa Schreb., above ; M. sylvatica Torr, below. (After A. Gray, Man. pl. 8.)

Fig. 45a--Bealia Mexicana, Scribner (provisional); C, Empty glumes; C. 2., Dorsal view of expanded empty glume; $D$ and $E$. Flowering glume and palea; $D$, Dorsal view of flowering glume; $\boldsymbol{S t}$, stamen; J, Pistil; K, Fruit. (Original.)
contracted or diffuse ; spikelets small, awns often bent or flexuose but rarely twister. Very varying in habit.

Species about sixty, mostly American, a few in Japan and in the mountains of Asia. Vosey, Thurber, Podnşmum Desv., Tosagris Beauv., Trichochorı Beauv.,

Clomena Beauv., and C'ulycouton Nutt. are all founded upon one or several species of this genus. Clomence Beanv., to which Bealia scrib. belongs, found in Mexico and Peru, forms a sub-genus characterized ly the twotoothed flowering glume which is awned between the teeth.*
109. (114) Brachyelytrum Beauv. Panicles with few spikelets; spikelets long and narrow; empty glumes minute; flowering glume with a long straight awn.

Species one (B. aristutum Beauv.), in North America.
110. Podophorus Philippi. Panicles open; flowering glumes longer than the empty ones, narrow, involute, with a pointed and short-bearded callus ; awn geniculate near the base, but not twisted. Rachilla prolonged, frequently bearing an awned, rudimentary glume.

Species one ( $P$. bromoides Ph.), upon the island of Juan Fernandez.
111. (116) Lycurus Kunth (Pleopogon Nutt.). Spikelets small, narrow, the upper one of each pair of, the lower of or sterile. Lower empty glumes with $2-3$ awns, the upper one and the flowering glume with only one.

Species two, in Mexico and New Mexico.
112. (115) Perieilema Presl. Panicles spike-like or interrupted, covered with the mumberless awns (especially of the sterile spikelets). Palea and all the glumes awned.

Species three, in Mexico and tropical America.

[^4]SUb-TRIBE 2.-Phleoideæ.
Fruiting glumes delicate. Stigmas with short branches, projectincs from the apex of the spikelets.
113. (106) Cornucopiæ L. A small, brauched grass with minute spikelets in small heads; the pedicels be-

Fig. 46.-Cornucopioe cucullatum L. (After Schreber, Beschreib., pl. 41.)
come curvel at maturity, when they separate at the jointed base and bore into the ground.

Species one ( $C$. cucullatum L. ), in the Orient (Fig. 46).
114. (105) Crypsis Ait. (Antitragus Gärtn.). Spikelets small, awnless ; palea one-nerved; stamens two ; fruit a utricle, the seed adhering to the spikelet for some time after it is expelled.

Species one ( $C$. acmlerta Ait.), in the Mediterranean region and upon the saline soils of the interior.
115. (120) Heleochloa Host. (Pecher Pourret). Like the precerling, except that the palea is two-nerved and the stamens three. The false spikes are subteuted by a single leaf.

Species eight, in the Mediterranean region and in the temperate parts of Asia. Rhizoceplutus Boiss. belongs
here. [H. schoenoides (Crypsis schounides Lam.) has been introduced into N. America, and become estahlished about Philadelphia.]
116. (121) Maillea Parl. A dwarf
 grass with short, false spikes and much compressed, awnless spikelets. Stamens two ; palea one-nerved.

Species one (M. Urvillei Parl.), upon the Cyclades, Sporades, and also in Sardinia.
117. (122) Phleum L. Inflorescence usually in cylindrical, exserted, false spikes. Keel of the empty glumes extending into a point or short awn ; flowering glumes awnless. Stamens three; palea twonerved.

Species ten, in the temperate zones (except in Australia). $P h$. pratense L., "Timothy" (Fig. 47), has its empty glumes truncate, with a long fringe upon the keel. Common in Europe. A very valuable grass for hay in heavy soils.

The section Chilochlon (Beauv. as

Fici. 7\%. - Ihleum pratense 1. B.r., Spikelet with ripe fruit. (After Nees, Gen. Germ. pl. 10.)
a genus, Achnodon Link) has the rachilla prolonged beyond the palea. Ph. Boehmeri, of central Europe, also belongs here.
118. (117) Echinopogon Beaur. (Hystericinc Steud.). False spike bristling with the long, straight awns of the flowering glumes. Empty glumes awnless.

Species one (E. ovatus P. B.), in Australia and New Zealand.
119. (107) Alopecurus L. False spike cylindrical or ovate. Empty glumes awnless, nsually fringed on the keels; flowering glume usually with a bent, dorsal awn; Iodicules none, and palea often wanting. Flowers decidedly proterogynous.

Species twenty, in temperate Europe and Asia, a fow also in North and South America and Australia.
A. pratensis L., "Meadow Foxtail," has acute, hairy, empty glumes counate below the middle; root-stock creeping; culms leafy. An excellent fodder-grass, especially for wet meadows. [A. occidentalis Scribn. is a valuable hay grass in the Rocky Mountain region.] The species having a distinct palea are Colobache Beauv. (as a genus) ; Tozettic Savi is A. utriculatus L.
120. (123) Mibora Adans. (Chemagrostis Borkh.,

Fig. 48.-Alopecurus pratensis. (After Nees, Gen. Germ., I. \%.)

Fia. 49. - Mibora verna Adans. (After Nees, Gen. Germ., I. 6.)

Knoppio Sin., Sturmiu Hoppe). A delicate, dwarf grass with short setaceous leaves, slender spikes, and awnless glumes.

Species one (M. verna Aclans.), in Western Europe (Fig. 49).
121. (124) Coleanthus Seid. (Schmidtia Trattin). A
dwarf, prostrate grass with the base of the panicle enclosed in the inflated upper leaf-sheath. Stamens two, alteruating with the flowering glumes and palea. Grain projecting beyond the flower.

Species one (C'. subtilis Seid.) (Fig. 50), on the mudrly banks of rivers, lakes, and ponds. Distribution remark-

able : Bohemia, Moraria, Lower Austria, Tyrol, France, Norway, Amur, Oregon, and Washington.
122. (125) Phippsia Brown. Dwarf ; panicle mostly rnclosed in the leaf-sheath; spikelets minute; stamen one.

Species one ( $P$. rlypidn Br.), in the arctic polar regious, also on the higher Fjelden.

## Sub-TRIbE 3.-Euagrosteæ.

Fruiting glume delicate; stigmas pectinately branched, usually projecting from the sides of the spikelets.
123. (126) Sporobolus Brown (Iilfe Beaur. nou Adans., Agrosticulu Raddi, Ciryptostrchy.s Steud.) (Fig. 51). Panicles variable. Spikelets small, awnless, naked; flowering glume and palea usually exceeding the empty glumes. Palea bifid. Fruit a utricle; the expelled seed usually remains adherent for a time to the spikelet.

Species eighty, chiefly in temperate and tropical America, but also in the warmer parts of Africa and Asia. One species (S. pungens Kunth) in Europe. Perennial, meadow grasses of the American prairies. [S.cryptandrus Gray, a valuable forage-grass.] Diachyrimm Griseb. and Triuchyrium Hochst. are founded upon the erroneous conception of two separate palers the division or splitting of the palea arises mechanically during the ripening of the fruit.
124. (127) Epicampes Presl. Flowering glume with a delicate, often deciduons, or rudimentary awn on the point; fruit apparently a true caryopsis.

Species twelve, from California to the Audes, in the Argentine Republic. Crypsimu and Bunchea Foum. belong here.
125. (130) Chæturus Link. Panicle contracted, short. Spikelets very narrow, in twos or threes upon each hranchlet; flowering glumes somewhat shorter than the empty ones, awnless. Low, annual grasses.

Species two, C\%. fascicultatus Link and Ch. prostratus Hack. and Lange, upon the Therian Peninsula.
126. (131) Polypogon Desf. (Sontia Savi, Ruspulia and Nouorhoniskya Presl) (Fig. 52). Panicles contracted or spike-like, often interrupted. Empty glumes frequently hifid, their awns usually long and slender; flowering glumes awned. The numerous awns impart it bristly appearance to the inflorescence.

Species ten, in the warm temperate zones of locth hemispheres. Two in the tropics. P. Monspeliensis

Desf. and $P$. moritimus Willd. in the Mediterraneau region. [Introduced into North America.]
127. (50) Garnotia Brongn. (ATiquelia Nees, Berghausia Endlich). Spikelets small, in pairs along the branches of the usually expanded panicles. Flowering glumes with slender, slightly bent awns, or awnless.

Species eight, from Eastern India to Japan.
128. (48) Thurberia Benth. (Greenia Nutt. non Walk. et Arn., Sclerache Torr. non Brown). Spikelets narrow, solitary along the branches of the panicle. Empty glumes rather hard. Awn of the flowering glume geniculate, twisted below.

Species two (T. Arkansana and T. pilosa), Arkansas and Texas. Fig. 52.-Potypogon Monspeli. $\quad$ 129. (49) Limnas Trin. Pani-
$\begin{aligned} & \text { Hesis Desf. } \\ & \text { Germ., } 1.32 .)\end{aligned}$ After Nees, Gien. $\quad$ cles loose, few-flowered; all the
 glumes firm in texture ; empty glumes with three prominent nerves; awns dorsal near the base, hent and twisted ; styles connate below.

Species one (L. Stelleri Trin.), in Eastern Siberia.
130. (132) Arctagrostis Griseb. Panicles contracted, narrow, few-flowered. Spikelets large (for the tribe), awnless. Flowering glume herbaceo-membranaceous.

Species one (A. Tatifolin (triseb.), arctic-cireumpolar.
131. Cinna L. (134) (Alkela Adans., Blyttia Fries). Panicles elongated, many-fluwered, spikelets small; flowering glumes with a very short awn just below the point. [Rachilla usually prolonged, naked.]

Species two, C. pendula Trin. and C. armentinacen L., in Northern Europe and North America.
132. (129) Agrostis L. Panicles variable, usually diffuse and many-flowered; spikelets small, flowering
glumes thin-membranaceons, or hyaline, awnless, or often with a bent awn inserted below the middle of the back; two lateral nerves sometines also projecting into rery short awns; palea usually short, often minute or none.

Species abont one hundred, distributed over the entire globe, especially in the north temperate zone, where they constitute the more important meadow grasses, though the foliage is too low and too delicate to produce a great quantity of forage. A. alba L., "Fiorin grass" (Fig. 53), has a long ligule, pyramidal panicles which are contracted after flowering, and usually awnless spikelets. It is a valuable foddergrass, especially for moist lands, moors, etc.; the same is true of the related A. vulgaris With. ("Red Top"), which has a shorter ligule and panicles more open after flowering. A. nebulosa Boiss. \& Reut., a native of Spain, has extremely delicate panicles and very small spikelets; it is commonly cultivated for dry bouquets. The genus Tricho-
 dium Schrad. comprises those spe- Fig. 53.- Agrostis alba L. cies having the palea rudimentary or wanting. Bromidium has a spike-like panicle.
133. (136) Chætotropis Kunth. Distinguished from the preceding by its very compact panicle, fringed keel of the empty glumes, and distinct projection of the rachilla beyond the palea.

Species one (Ch. Chilensis Kunth), in Chili.
134. (135) Gastridium Beauv. Panicles dense, spikelike; spikelets narrow, shining; rachilla produced heyond the palea, flowering glumes one third as long as the empty ones, awnless or awned.

Species two, G. australe Beauv., G. scabrum Presl, in the Mediterranean region.
135. (137) Triplachne Tink. Panicles short, spike-
like, shining, flowering glume downy ; awns almost basal, geniculate.

Species one ( $T$. nitens Link), in the western countries of the Mediterranean region.
136. (133) Calamagrostis Roth (Figs. 54 and 55). Panicles very variable; hairs on the callus of the flowering glume sometimes short and sometimes

Fig. 51. - Calamarrostis IIalleriana D.C. (After
Nees, Gen. Germ., I. 31.) longer than the glume itself, which is usually thin-membranaceous and variously awned. Frequently reed-like in habit. The spikelets usually larger than those of Agrostis.

Sec. I. Epigeos Koch. Rachilla not produced; hairs on the callus usually long.

Species ten, in the north temperate zone of the Old World, including C. Epigeos (L.) Roth, C. litoren DC., C. lanceolata Roth, and C. Halleriana DC. Sec. II. Deyeuxia Beauv. (as a genus). Usually with a hairy prolongation of the rachilla; callus hairs shorter than in Sec. I, very rarely wanting.

Species over one hundred and twenty, distributed throughout all the temperate and arctic zones, also upon the high mountains of the tropics; about sixty species in the Andes alone. [Calamagrostis Tweedyi, Suliselorfii, Montanensis, and ambigun Scribn. are Rocky Mountain species.]

Acharte Fourn., Relchela Steud., Cinnastrum Fourn. are more or less anomalous species of this section.
137. (139) Cinnagrostis Griseb. Like the

Fig. 55.-Calamagrost is (Deyeuxias sylvatica. (After Nees, Gen. Germ., I. 34.) preceding, but with unisexual spikelets; rachilla with a long and very hairy prolongation ; callus short, bearded.

Species one (C. polygama Griseb.), in the Argentine Republic.
138. (141) Ammophila Host. (Psamma Beauv.) Panicles usually narrow and spike-like. Flowering glume
and palea chartaceous, somewhat indurated, awnless; spikelets comparatively large.

Species one, A. arundinaceu Host. ("Sand reed"), has long, creeping rhizomes, and cylindrical, false spikes. On the sandy coasts of Europe and the Atlantic States of N. America, rarely in the interior. This grass is frequently planted for binding the dunes and loose sands, as it penetrates these by a thick network of rhizomes that withstands the strongest washing of the waves. A cross (A. Baltica Link) is sometimes formed with Calamagrostis Epigeos Roth.

Obs. - Very nearly related to Ammophila are two N. American species, Calamagrostis brevipilis Gray and C. longifolia Hook., with the loose panicle of Calamagrostis, but the chartaceous tlowering glumes of Ammophila, distinct from both genera by the one-nerved flowering glumes; they may best be considered a separate genus, Calamoxilfie (Gray as a sect. of Calamagrostis). (Hackel in MS.)
[138a. Calamovilfa. Empty glumes mequal ; flowering glumes one-nerved ; rachilla not prolonged.

Species two, in N. America (C. brevipilis of the Atlantic coast, and C. Iongifolio of the western interior). These species are referred to Ammophita in B. \& H. Gen. Pl., vol. III, p. 1153.]
139. (138) Apera Adans. (Anemergrostis Trin.). Panicles loose, spikelets delicate ; rachilla prolonged, nakert. Awns four times as long as the flowering glumes, straight or somewhat geniculate.

Species two, in Europe and Western Asia. A. SpicuVenti Beaus. is often a troublesome weed in crops. [Introduced into United States about Philadelphia, etc.]
140. (142) Dichelachne Endl. Pauicles dense, long and narrow, bristly on account of the numerons awns; rachilla very slightly produced ; awns very long, somewhat flexuous, not bent.

Species two ( $D$. crinita and D. sciurea Hook.), from Australia to New Zealand.
141. (143) Trisetaria Forsk. (Anomalotis Steud.). Panicles long and narrow; rachilla prolonged, perlicel-like; middle awn from the back of the flowering glume, geniculate, twisted below ; lateral awns delicate, straight.

Species two (T. lineeris Forsk. and T. quinquesetc Hochst.), in Egypt and Abyssinia.
142. (118) Diplopogon Brown (Dipogonite Beatuv.). False spikes capitate; rachillar not prolonged; palea with two awns; middle awn of the flowering glumes tendril-like below, recurved above.

Species one ( $D$. setucens Brown), in Western Australia.
143. (144) Pentapogon Browu. Panicles uarrow, deuse ; rachilla prolonged, perlicel-like; middle awn of the flowering glume dorsal, twisted

Fig. 56.-Lagurus ovatus L. After Nees, Gen. Germ., I. 45.$)$ below, at length geniculate, longer than the four lateral awns.

Species one ( $P$. Billardieri Brown), in Tasmania and Victoria.
144. (145) Lagurus L. Panicles spike-like or capitate ; spikelets thickly clothed in the fine, woolly hairs covering the empty glumes, from which project the long dorsal awns of flowering glumes ; lateral awns short.
Species one (L. ovatus L.) (Fig. 56), in the Mediterraneau region; frequently cultivated for dry bouquets.

## Tribe IX.-Avenee.

Spikelets 2-> -flowered (only one-flowered in Anisopog(m); inflorescence in panicles, rarely in spikes; all flowers $\begin{gathered}\text { or one of } \\ \text {; empty glumes often persistent }\end{gathered}$ or remaining after the fruiting glumes have fallen, usually longer than the flowering glumes, the latter usually awned on the back, sometimes near the point; awn geniculate, rarely nearly straight ; palea two-keeled; style short or mone. Stigmas feathery, protruding aloore the base or middle of the spikelet. Grain usually furrowed; embryo small ; starch-grains compound.
A. Spilielets readily decirnous as a whole. . 145. Holcus.
B. Fruiting glumes deciduous, empty glumes persistent.
a. Spikelets strictly two-flowered, rachilla not prolonged.
$\alpha$. Empty glumes cartilagiuous on the back; keel with pectinate teeth. . . . 146. Prionachne. $\beta$. Empty glumes membranaceous.
I. Flowering glumes long ciliate-fringed on the back or margins ; palea naked ; empty glumes broad, many-nerved. 147. Eriachne.
II. Flowering glumes and palea, especially the latter, with a long fringe on the keels. Empty glumes narrow, 1-3-nerved. 148. Zenkeria.
III. Flowering glumes and palea naked.

1. Upper flower in each spikelet on a rather long pedicel, smaller than the lower one, \&. . . . 150. Cœlachne.
2. Both flowers nearly sessile, of equal size, $\stackrel{\square}{\text {. }}$

* Palea many-nerved. 149. Micraira. ** Palea two-nerved.
$\dagger$ Empty glumes semi-globose. Panicle spike-like. 151. Airopsis.
$\dagger$ Empty glumes not semi-globose. Panicle expanded.

Empty glumes evidently longer than the flowering glumes.
$\triangleleft$ Flowering glume truncate, slightly three - toothed, awnless. 153. Antinoria. $\triangleleft \triangleleft$ Flowering glumes twotoothed, awned.
152. Aira. OO Empty glume shorter than the flowering glume.
154. Molineria.

Note.-Compare Isuchne.
b. Spikelets $2-\infty$-flowered (except Anisopogon), rachilla prolonged beyond the upper flower. $\alpha$. Flowering glume awnless or with a short terminal awn. Spikelets small. . 155. Achneria. $\beta$. Awn of the flowering glume upon the back (i.e.,
rising from below the teeth of the point, not between them).
I. Spikelets in an open (rarely spike-like) panicle, not in a true spike.

1. Flowers all $\nsucc$ or the upper ones $\hat{\delta}$, or sterile.

* Grain free, unfurrowed. Spikelets usually small (less than 1 cm . long). O Flowering glumes finely erosedentate, or two-lobed, or with the edges entire.
$\triangleleft$ Awns not articulated, the point fine. . . 157. Deschampsia. $\triangleleft \triangleleft$ Awns articulated, the point club-shaped.

156. Corynephorus.

O○ Flowering glume cleft or twotoothed with the teeth sometimes produced into awns.
$\triangleleft$ Lower flower awnless, spikelets narrowly oblong.
159. Ventenata.
$\triangleleft \triangleleft$ Lower flower awned. Spikelets elliptical-lanceolate.
158. Trisetum.
** Grain furrowed, usually adherent to the glumes; spikelets over 1 cm . long. O Only two nerves of the flowering glume reach the point ; grain hairy at the apex. . . . 160. Avena.
O○ Nerves five, prominent, all extending to the point; grain naked.
161. Amphibromus.
2. Upper flower $\underset{\succ}{ }$, the lower $\hat{b}$ and strongly awned. . . . . 162. Arrhenatherum.
II. Spikelets in a true, two-ranked, simple spike. . . . . . . . 163. Gaudinia.
$\gamma$. Awns from between the lohes or teeth of the flowering glume; the teeth also frequently awned.
I. Spikelets two-flowered, upper flower $\succcurlyeq$ or

1. Spikelets in threes, terminal on the branches of the panicle. 164. Tristachya.
2. Spikelets solitary, terminal on the branches of the panicle.

## 165. Trichopteryx.

II. All the flowers $\underset{+}{ }$, or the upper imperfect.

1. Spikelets one-flowered, very large.
2. Anisopogon.
3. Spikelets $3-\infty$-flowerect. 167. Danthonia.

Note.-Compare the Festucere; Graphephorum, Schismus, Dupontia, Dissanthelium (all awnless).
145. (157) Holcus L. (in part). Spikelets paniculate, two-flowered, upper flower of (rarely ¢), awned; lower $\wp$, awnless, its Howering glumes finally indurated, shining; empty glumes keeled, the upper one often short-awned.

Species eight, in Europe and
 North Africa, especially the western part, one in Cape Colony. H. lanatus L. (Fig. 57), with woolly or downy leaves, is of some value for forage.
146. (147) Prionachne Nees (Chondrolana Nees [Prionanthium Desv.]). Panicle narrow, spike-like; spikelets
 awnless, somewhat like those of Fig. 57.-Holcus lanatus Phalaris.
L. (After A. Gray, Man. pl. 12.)

Species one ( $P$. dentate Nees), in South Africa.
Ktenosachne Steud. may also belong here.
147. (146) Eriachne Brown (Fig. 58). Panicle lonse or dense. Empty glumes many-nerved; flowering glumes awnless or with fine terminal awns, finally somewhat indurated. Two flowers "apparently inserted at the same point, without any development of rachilla" (Benth. Notes, Gr. 92).

Species about twentr-two, all but two Asiatic and Australian.

Megalachne Thwaites, belongs here.
148. (148) Zenkeria Trin. (Ampliclonce. Nees (in part)) .

Fig. 58.-Eriarhme glamea R . Brown. (After Kunth, Rev. (iram. pl. 64.) Panicle loose, empty glumes 1-3nerved ; flowering glomes awnless, the two flowers closely approximate.

Species two, East Indian peninsula and Ceylon.
149. (149) Micraira F. Müll. A low, matted grass, with appressed, subulate leaves; spikelets very small, awnless, in loose panicles.

Species one (M. subulifotia Müll.) in Queensland.
150. (150) Cœlachne Brown. A very delicate, often prostrate grass with narrow panicles and small, round, awnless spikelets. Flowers divergent.

Species three, in East Indies, South China, and tropical Australia.
151. (151) Airopsis Desv. A delicate amnual grass with nearly cylindrical panicles. Spikelets small, globose, shining, awnless; the two flowers very closely appressed to each other. Species one ( $A$. globosa

Fig. 59.- Aira caryophyllea L. (After what inclurated. Delicate auNees, Gen. Germ., I. 44.) Desv.), in Southwestern Europe and Northwestern Africa. 152. (152) Aira L. (in part) (Fussia Schur.). Spikelets small, usually in loose panicles. Empty glumes thin-membranaceous, the two flowers closely superposed. Flowering glumes usually awned on the back (awn rarely wanting), finally somenual grasses with slender panicle-branches.

Species six, throughout Europe, especially in the South, and in North Africa, one species in all temperate comutries. A. elegans Gaud. and A. caryophylled L. (Fig. $59)$ are frequently cultivated for dry bouquets under the false name of Agrostis elegans. Fiorinia Parl. is au awnless species.
153. (152) Antinoria Parl. In general like the precerling, but the flowers are separated by a manifest internode of the rachilla, and the flowering glumes are different.

Species two, in Southwestern and Southern Europe.
154. (152) Molineria Parl. Like the preceding, but with the flowers projecting from the empty glumes. Flowering glumes truncate or slightly toothed, awnless or with short awns.

Species three, Western and Southern Emope to Asia Minor. Periballia Trin. is a species with a short, twotoothed flowering glume.
155. (155) Achneria Mumo (non Beauv.). Spikelets small, in panicles; flowers separated by a short internode of the rachilla, somewhat shorter than the empty glumes, often hairy. Peremial grasses. Leaves frequently convolute.

Species eight, in Sonthern and tropical Africa (Eriachne of Nees, in Flora Afric. Austr.).
156. (153) Corynephorus Beauv. (Weingrertneria Bernhardi). Grasses with the habit of Aira, but with the rachilla prolonged, and club-shaped awns with a circle of short bristles at the point of articulation.

Species three, in Europe. C. conescens Beatr. (Fig. 60 ) grows in sand fields ; it is a hardy but a poor pasture grass.
157. (154) Deschampsia Beauv. Spikelets rather small, two-flowed (rarely with an imperfect third flower); panicle loose or compact; florets separated by an internode; flowering ghmes exceeding the empty ones; awns slender.

Species twenty, in all cold and temperate countries, a few in the high mountains of the tropics.

Sec. I. Campella Link (as a genus). Awns straight.
1). crespitosu Beauv. (Fig. 61), with large, open panicles, narrow, rough, hard leaves, forms a thick turf, and is cosmopolitan. It is of little value for fodder.

Fig. 60.-Corynephorus canescens Bv. (After Nees, Gen. Germ., I. 42.)

Fig. 61.-Deschampsia coespitosa Beauv. (After Nees, Gen. Germ., I. 43.)

Fig. 62.-Trisetum pratense Pers. (After Nees. (Gen. Germ., I. 46.)

Sec. II. Avenella Parl. (as a genus) (Lerchenfeldic Schur.). Awns geniculate (D. flexuose Trin. and others).

Sec. III. Vuhorler Fries (as a gemus). Like Section II, but with entire flowering glumes (Airidium Steud., Peyritschia Four., and Monandraira Desv. are more or less anomalous species).
158. (158) Trisetum Pers. Spikelets in an open or close panicle, two-flowered, rarely 3-6-flowered; empty glumes unequal, 1-3-nerved; flowering glumes keeled; callus and rachilla usually hairy; lateral teeth of the flowering glumes frequently produced into awns; middle awn geniculate.

Species about fifty, from the Arctic regions through
the north temperate zone, the high momntains of the tropics to the south temperate zone.
T. pratense Pers. (Avenc flavescens L.), "Golden oats" (Fig. 62), has a loose panicle and yellow, shining spikelets, and is a valuable fodder-grass. T. subspicatum Beauv. is arctic, alpine, and antarctic. Trichete Beanr. and Acrospelion Bess. are species of this genus.
159. (159) Ventenata Kölr. Like the precerling, but with the flowering glumes of the lower floret entire and awnless, and the spikelets longer and narrower ; empty glumes 3-5-nerved.

Species three, Europe ( $V$. avenacea Kölr.) and the Orient.
160. (160) Avena L. Spikelets 2 - 6 -flowered (rarely one-flowered) in panicles. Empty glumes membranaceous, unequal ; flowering glumes rounded on the back, 5-9-nerverl, often two-toothed; awn dorsal, geniculate, twisted below (sometimes wanting or straight in cultivated forms). Callus of flowering glumes and the rachilla often hairy; ovary hairy all over or ouly at the point; caryopsis fusiform, deeply sulcate.

Species over fifty, in the temperate zones of the Old and a few in the New World.

Sec. I. Crithe. Ammals. Spikelets nodding ; empty glumes many-nerver. A. sutiva L., cultivater Oat (Fig. (63), with the awns of the persistent flowering glumes straight or none, has originated, perhaps, from the wild Oat (A. fotuc L.), which has geniculate awns and deciduons flowering glumes; or from a similar species of which there are several in Southern Europe and Western Asia. Oats were cultivated in very ancient times in Europe, aud extend as far as $69^{\circ} .5$ north latitude. It is the principal grain of Norway and Sweden, where it is used partly for mush, and partly for griddlecakes ("Fladbrode"). Oatmeal is used in the same way in Scotland, Irelaud, and on the Shetland and Orkney Islauds. In the rest of Europe and in North America the plant is cultivated mainly as food for horses. In China there is a naked oat (see below) which is used in medicine ; in Europe also water-gruel, made with oat-
meal, is used as a mildly stimulating drink (hence the ofticinal Avence fructus excorticutus). It is also raised for green fodder. There are two principal races: Panicled oats, with expanderl, and "Bamer oats" (A. orientrlis Schreb.), with contracted, one-sided panicles. Each of these is divided into the chaffy and naked-fruited varieties, and the first, according to the color of the flowering glumes, into white, yellow, gray, brown, and black oats. In the naked oats ( $A$. mudu L.) the rachilla is pro-

Fig. 63.-Avena sativa L. (After Nees, Gen. Germ., I. 48.)
longed and bears $4-6$ flowers which project beyond the empty glumes; the flowering glumes are thin-membranaceous and allow the fruit to fall out. The "wild oat" (A. fatucu L.) is ofteu very troublesome as a field weed in crops, especially in Southern Europe. The "Hairy oats" (A. strigosa Schreb.) and the "Short oats" (A. brevis Roth.) are distinguished from A. sativa by the pedicellate lower flower and the usmally two-awned spikelets; in the first the flowering glume is drawn out
into two fine, awn-like points; in the latter into two short, coarse teeth ; the fruit is also shorter aud broader. The culture of these two varieties has been given up in most countries on account of the small protits clerived from them ; they can be utilized advantageonsly only on very light, sandy soils. In Portugal, Spain, the Shetland and Orkney Islands, and in Mechlenburg, Holstein, etc., Hairy oats (A.strigosa) are here and there cultirated. Both species occur as weeds, however, especially among common oats.

Sec. II. Avenastrum (Heuffelia Schur., Helicotrichum Bess.). Peremmials. Spikelets upright; empty glumes five-nerved. A. pubescens, "Downy oats," with downy lower leaves, is a good folder-grass. [Avena Hookeri Scrib. (A. versicola Hook. non Vill.) with the habit of A. protensis L. is common in the Rocky Mountain region of the Northwest.]
161. (162) Amphibromus Nees. Spikelets S-10-flowered, loosely panicled ; awns slender, geniculate.

Species one (A. Neesii Steud.), in Australia.
162. (163) Arrhenatherum Beauv. Habit of Avenc, Sec. II; but the spikelets are somewhat smaller, and the two flowers in each are different (as to sex). The flowering glume of the lower floret is awned from the base, while that of the upper is awned from the point or awnless.

Species six, in Europe, North-
 ern Africa, TVestern Asia. A. Fig. 64.-Archenatherum arenaavenaceum Beauv. (Avena elatior Germ., L. 49.)
L.) (Fig. 64) with expanded panicles and naked, shining spikelets is the French "Ray grass." It is native in Central and Southern Europe, and much cultivated in North America ("Randall grass," "Evergreen grass"), a rery good and productive grass for chalky soils.
163. (161) Gaudinia Beauv. (Arthrostachya Link) (Fig. 65). Amuals with the habit of Lolium, and spikelets as
in Avena, many-flowererl, but singly sessile in notches of the articulate rachis ; awns slender.

Species two, one, G. frogitis Beauv., in the regions of the Mediterranean, the other (G. geminiflora J. Gay), on the Azores.

Fig. 65.-Gaudinia fragilis Beauv. (After Fig. 66.-Danthonia provincialis Nees, Gen. Germ., I. 81.)
DC. (After Nees, Gen. Germ., I. 50.)
164. (164) Tristachya Nees (Monopoyon Presl). Panicles loose; flowering glumes of the f flower awnless, that of the of flower deeply cleft, and with a long, geniculate and twisted awn.

Species eight, in tropical America, the others in tropical Africa and Western Asia.
165. (165) Trichopteryx Nees (Loudetia Hochst.). Distinguished from the preceding ouly by the solitary spikelets. Flowering glume often hairy.

Species ten, in tropical and Southern Africa, one of them also in Brazil.
166. (166) Anisopogon Brown. Pamicles loose, with solitary, very large ( 4 cm . exclusive of the awns) spikelets ; Howering glumes five-cleft, four lateral points finely awned, and the middle one with a strong geniculate awn.

Species one (A. avenucpus Brown), in Australia.
167. (167) Danthonia DC. Pamicles lonse or deuse; flowering glumes rounded on the back, 7-9 nerved, frequently fringed, two-cleft, the points sometimes two-
parted and ending in awns; middle awn flattened at the base, usually geniculate and twisted.

Species about one hundred, in the warm and temperate zones of both hemispheres, more than half of them in South Africa. [D. compressa Austin, on the mountains of North Carolina and Tenuessee, is valuable for grazing.]

Sec. I. Himantochute. The two teeth of the flowering glume undivided. D. provinciulis DC. (Fig. 66), from South Europe to Vienna. Crimipes Hochst. and Streblochrete Hochst. are species of this section.

Sec. II. Pentuschistis. Teeth of the flowering glumes again two-toothed and often produced into awns. Pentameris Beauv. and Chatobromus Nees belong here.

## Tribe X.-Chloridee.

Spikelets one- to many-flowered, in two series upon the outer side of the continuous rachis of the spike or raceme; flowering glumes deciduous with the fruit; the usually two empty glumes rarely falling with them. Palea twonerved; styles distinct; stigmas projecting from the sides, rarely from just below the aper, of the spikelets; grain free, unfurrowed ; starch-grains usually compound, rarely simple.
A. Flowers of all the spikelets hermaphrodite.
a. One چै flower (rery rarely two) in each spikelet. $\alpha$. No sterile glumes or を flowers, and only rarely a short projection above the $\begin{array}{r}\text { flower. }\end{array}$
I. Spikelets awnless [sometimes short-awned in Spartina].

1. Spikelets falling off from the rachis entire.
2. Spartina.
$2^{\circ}$. Empty glumes not deciduous.

* Spike terminal, slender.

168. Michrochloa.
** Spikes 2-6, digitate. . 169. Cynodon.
*** Spikes many along a common axis.
$\dagger$ The axis slender ; flowering glume longer than the empty ones.
169. Schedonnardus.
$\dagger \dagger$ The axis bordered by a narrow membrane; flowering glumes many times shorter than the empty ones.
170. Craspedorhachis.
II. Spikelets distinctly awned.
$1^{\circ}$. Spikes terminal, one to four in number.
171. Schœenefeldia.
$2^{\circ}$. Spikes numerous, approximate at the end of the culm. . . . . 178. Monochæte.

Note.-Compare Nardus with one spike, one pistil, oue indistinct empty glume.
$\beta$. One to several empty glumes above the $\psi$ flower ; these are ofteu small or awn-like, rarely with a $o$ flower in their axils.
I. Empty glumes four, the two upper often having a palea in the axil but bearing no flower. . . . . . . . 173. Ctenium.

## II. Empty glumes two.

$1^{\circ}$. Spike one, terminal.

* Spikelets awnless. 172. Harpechloa. ** Spikelets awned. 174. Enteropogon.
$2^{\circ}$. Spikes two to many (occasionally resembling short fascicles).
* Spikes in false whorls or at least closely approximate.
$\dagger$ Flowering glume of the $\stackrel{\text { flower }}{ }$ with one awn, or awnless.

175. Chloris.
$\dagger \dagger$ Flowering glume of $\stackrel{\circ}{ }$ flower with three awns. 176. Trichloris.
** Spikes remote or the lowest only approximate.
$\dagger$ Spikelets scattered or remote.
176. Gymnopogon.
$\dagger \dagger$ Spikelets crowded.
Flowering glume plumoseciliate. 182. Melanocenchris.
O○ Flowering glume not plumose. . . 181. Bouteloua.
Note.-Compare the one-flowered Leptochloa species.
b. Each spikelet with $2-3$ ¢ flowers.
$\alpha$. Spikes terminal, solitary or $2-3$ approximate and upright; spikelets awned.
I. Flowering glumes with three awns, the middle one from below the entire point, the lateral ones (often short) beginning lower down. . . . . . 183. Tripogon.
II. Flowering glumes with one awn below the entire point. . . . 184. Lepidopironia.
III. Flowering glumes with one awn below the two obtuse lobes of the point.
177. Tetrapogon.
IV. Flowering glume deeply three-cleft; lateral divisions pointed, the middle one prolonged into a strong awn.
178. Astrebla.
$\beta$. Spikes 1-3, short, terminal, not digitate, spikelets awnless. . . . . . 192. Cœlachyrum.
$\gamma$. Spikes numerous, along a common axis or digitate at its apex; spikelets awnless.
I. Spikelets deciduous as a whole.
$1^{\circ}$. Empty glumes four. . 187. Tetrachne.
$2^{\circ}$. Empty glumes two. 189. Beckmannia.
Note.-Compare Leptochloa bipinnata Hochst.
II. Empty glumes two, persistent, flowering glumes deciduous.

* Empty glumes with a subulate awn, projecting beyond the flowering glumes.

188. Dinebra.
** Empty glumes awnless or mucronate pointed, shorter than the flowering glume.
$\dagger$ Spikelets densely crowded, spikes usually digitate.

O Spikes with terminal spikelets.
190. Eleusine.

OO Spikes without terminal spikelets; the rachis drawn out to a point and projecting beyond them. . 191. Dactyloctenium.
$\dagger$ Spikelets distinctly alternating; spikes remote. . 193. Leptochloa.
Note.-Compare Wangenheimia, Festuca, also Trichloris with three awns.
B. Plants diœcious, rarely monocious, the two sexes very untike.
a. \& inflorescence capitate, of spikelets 2-3-flowered. 194. Buchloē.
b. \& inflorescence a loose, one-sided spike, of spikelets one-flowered.
195. Opizia.
168. (168) Microchloa Brown. Low, ciespitose, delicateleaved grasses, with long, frequently curved spikes.

Species three, two African, the third (M. setacea) distributed throughout tropical zone.
169. (170) Cynodon Pers. (Capriola Adans., Fibichice Kïl., Dactylon Vill. (in part)). Spikelets small; flowering glumes usually longer
 and broader than the narrow empty ones, ciliate on the keel; spikes slender, radially divergent.

Species four, three in Anstralia, the fourth ( $C$. Dactylon Pers. (Fig. 67) "Dog's tooth," with long creeping runners and $3-5$ digitate spikes) cosmopolitan. This species covers the ground extensively in sandy soils, and although it has delicate leaves, it withstands protracted drouths. In the S. States ("Bermuda grass"), it is the Fie. 6r.-Cymodon Dactylon Pers. (After most important grass for pasturage, and, as in Hindostan, it is prized for fodder, both for horses and cows. The Hindoos consider it sacred. In Bengal it is called "Durba," in N. India " Dub," and in the Deccan "Hariali." In Europe it has been little appreciated.

Its rhizome ( $R h$. Graminis Italici) is used in medicine like that of the Paspulum distichum (see p. 73).
170. (19) Spartina Schreb. (Trachynotia Michx., Limnetis Pers., Solenachne Steud.). Spikes two to several, usually upright, approximate, rarely remote; spikelets large, compressed; empty glumes unequal ; as long or nearly as long as the flowering glume ; embryo nearly as long as the fruit.

Species seven. Maritime grasses, three of which are common to the Atlantic coast and to the Mediterranean shores (Sp.stricta Roth); two in the Western prairies, one in Montevideo, one upon Tristan da Cunha, Ainsterdam, St. Paul. Coarse grasses, of not much value as fodder.
171. (169) Schœnefeldia Kunth. Spikes 2-4, long. Spikelets deusely crowded, sub-pectinate. Striking in appearance on account of the very long slender awns which impart to the spikes an elegant crinate aspect.

Species three, tropical Africa; one East Indian.
172. (171) Harpechloa Kunth. Spikelets crowded, pectinate; flowering glumes of $\nsucc$ flower broad, compressed, obtuse, long-fringed; above the of flowep are $1-3$ small glumes that are either empty or with of flowers; spikes dense, often falcate.

Species two (H. capensis Kunth), in SouthoAfriêall : C
173. (172) Ctenium Panzer (Campulosus Desv, Monocerc Ell.) (Fig. 68). Spike one, rarely 2-3, usually curved; spikelets densely imbricated, pectinate ; second empty glume awned on the back; awn stout, divergent; flowering glume of $\wp$ flower with a very slender awn below the point; one to two empty or of bracts above the flowering glume.

Species seven, four in South and North America, three in Africa and the Mascarene Isles.
174. (173) Enteropogon Nees. Spikes long, often curved ; spikelets imbricated; flowering glume of the $\ngtr$ flower with a slender awn below the point; 1-2 empty or of bracts above.

Species four, in East India, tropical Africa or the Mascarene and Seychelles Islands.
175. (174) Chloris Sw. (Fig. 69). Empty glumes narrow, very acute; flowering glumes broader, usually two-

Fig. 68.-Ctenium Americanum Schrank. (After A. Gray, Man. pl. 9.)

Fig. 69.-Chloris barbata Sw. $O$, Sterile glume. (After Trin., Spec. Gram. pl. 306.)
cleft, frequently ciliate; one to several empty glumes above, which are usually broadly truncate and often awned.

Species about forty, in all warm countries, except Europe. Elegant grasses, some of which (Ch. gracilis Dur. for example) are cultivated as ornamental plants. The species with awnless flowering glumes compose the section Eustachys Desv. (as a genus), Schultesia Spreng.
176. (176) Trichloris Fournier. Spikes erect, rather slender, approximate, or in elongated panicles, clothed with the numerous delicate awns. Spikelets sometimes $2-3$-flowered ; sterile bracts reduced to awns.

Species two, in Mexico, Texas, Arizona; two in Chili and one in Argentine Republic. That in the latter country (Tr. Blanchardiana Hack.) is as yet undescribed, but has long been known to gardeners as Chloropsis or Chloridopsis Blancherdianc, and is prized as an ormamental grass ; the one in Arizona is perhaps identical with it.
177. (177) Gymnopogon Beauv. (Anthopogon Nutt., Dichutarice Nees). Flowering glume a little broader than the empty glumes, awned below the two-cleft apex; sterile glumes often reduced to awns; spikes delicate, at first erect, finally divaricate-spreading or reflexed.

Species six, all, except one in Ceylon, American. Leaves short, rather broad and rigid.
178. (178) Monochæte Döll. Like the preceding, hut the rachilla is not produced beyond the flowers; spikes many, densely flowered.

Species one (M. fustigiata Düll.), in Brazil.
179. (179) Schedonnardus Steud. Spikes loosely flowered, remote on a common rachis, spreading; flowering glume finally indurated, linear, acuminatepointed.

Species one (Sch. Texanus Steud.), in N. America.
180. (180) Craspedorhachis Benth. Like the preceding, but the flowering glume and palea are very delicate, and so small as to appear like minute scales.

Species one (C. Africana Benth.), in tropical Africa.
181. (181) Bouteloua Lagasca (Eutriana Trin., Actinochloa Willd.)
 (Fig. 70). Spikes very variable, Fia. ro.- Bonteloua racemosa sometimes consisting of many and
Lag. (After Asa Gray, Man. p1. 9.) sometimes of $1-3$ spikelets; in the latter case they resemble solitary spikelets, but are distinguished by the prolongation of the axis beyoud the spikelets; flowering glumes with $3-5$ teeth, of which $1-3$ bear awns or mucros; upper sterile glumes usually reduced to awns.

Species about thirty, especially abundant upon the plateaux of the southwestern United States, where they form a large part of the prairie-grass ("Mesquite" or "Grama grass") and furnish excellent grazing for stock.

Sec. I. Chondrosium Desv. (as a geuus). Spikelets pectinate, numerous in each of the more or less falcate
spikes; upper sterile glumes usnally three-awned.- $B$. hirsuta Lag., Illinois to Mexico.

Sec. II. Atheropogon Muhlenb. (as a genus) (Heterostegu Desr.). Spikelets few (less than twelve) in mauy short spikes; upper sterile glumes viriable (see Fig. 70). -B. racemosa Lag., New York to Peru.

Sec. III. Triather" Desv. (as a genus) (Avistirlium Encll., Trirena Kunth). Spikelets either single or in twos or threes in each of the mumerons spikes; upper sterile glume three-awned.-B. cristidoides Griseb., in Mexico, California, etc.

Sec. IV. Polyodon Kunth (as a geuus) Triplatliera Endl.). Like Sec. III, but with 2-3 sterile bracts abore the $\nleftarrow$ flower; sterile bract with $3-5$ awns united in a fascicle.-B. multiseto Benth. in S. America.-B. Texana Wats. in Texas.
182. (182) Melanocenchris Nees (Ptiloneilemre Steud.). Spikes very short, sub-globose, very remote, finally deciduous. Low annuals.

Species three, in Hindostan and tropical Africa.
183. (183) Tripogon Roth. (Plagiolytrom Nees). Spikes terminal, elongated, solitary ; spikelets sub-imbricated, many-flowered, the 1-2 upper flowers smaller, z, or sterile. Small, ciespitose grasses with very harrow leaves.

Species eight, in East India and tropical Africa.
184. (184) Lepidopironia Richard. May belong to the preceding ; it differs only in the uni-aristate flowering ghme, which is covered with long woolly hairs.

Species one, in Abyssinia.
185.) (185) Tetrapogon Desf. (Cryptochloris Benth.). Spikes solitary or in twos or threes, usually clothed with silky hairs ; spikelets crowded, 2-3-flowered, broad.

Species five, four in North Africa, Alorssinia, and Western Asia. One (C'ryptochloris) of doubtful origin (in Patagonia?).
186. (186) Astrebla F. Müll. Spikes terminal, solitary or in pairs ; spikelets large, thickened ; empty glumes and flowering glumes many-nerved, the latter clothed with silky hairs.

Species two or three. A. pectincte and A. triticoides F. Müll. in Australia.
187. (189) Tetrachne Nees. Spikes remote, with densely crowded spikelets ; leaves terete, convolute.

Species one (T. Dregei Nees), in South Africa.
188. (188) Dinebra Jacq. Spikes short, numerous, scattered along a common axis, finally reflexed.

Species one (D. Arctbica Jacq.), a low amual in Northern and tropical Africa to Hindostan.
189. (6) Beckmannia Host. Spikelets broad, compressed, crowded, two-flowered. Empty glumes navicular, inflated on the back; flowering glumes narrower, keeled, pointed, but awnless.

Species one (B. erucreformis Host.). Eastern and Southern Europe, temperate portions of Asia and North America. [Specimens from America have one-flowered spikelets.]

Fig. 71.-A, Eleusine Coracana Gärtn. (After Schreber, Bschr. pl. 35.) B, S, Spikelets of E. Indica Gärtn. (After A. Gray, Man. pl. 9.) K, Utricle. S. seed.
190. (191) Eleusine Gürtn. Spikes digitate or rarely scattered; spikelets many-flowered, crowded; glumes closely imbricate, diverging, compressed and keeled, obtuse or mucronate-pointed; pericarp rery delicate.

Species six, mostly in the tropical and sutb-tropical
zone of the Old Torld ; one (E. Indica Gürrtn.) is a weed in all warmer comutries. E. Corucumu Gairtu. ("Korakan" or "Dagussar" "Mandua" in N. India, "Marua" in Bengal, "Ragi" in S. India) has thick spikes, and a seed which is marked with very fine comb-like lines. It is probably derived from E. Indica (see above), whose oblong seeds are marked with more distinct comb-like lines, and whose spikes are more sleuder. "Korakan" is cultivated in E. India, Sunda Islands, S. China, Japan, and especially throngh the whole of Africa. In many parts of Africa it forms the principal food in spite of the bitter taste of the flour. A kind of bread or unlearened cake is made from it. In Abyssinia and Niam Niam a tolerably good beer is brewed from it. In India it is much prized, as it yields good harvests from very poor soil.
191. (191) Dactyloctenium Willd. Empty glumes strongly mucronate-pointed. The pericarp is absorbed before the fruit is ripe.

Species one (D. Agyptiacum Willd., with several varieties), which occur's as a weed throughout all warm countries. A decoction is prepared from the seeds, which is used in Africa for inflammation of the kidneys.
192. (230 § ) Cœlachyrum Nees. Small, annual plants, with short spikes and no prolongation of the axis; fruit a utricle whose pericarp is easily loosened at an early period, leaving the shield-shaped seed marked with prominent radial lines.

Species two, C. brevifolium Nees in Arabia and $C$. Indicum Hack. (Eragrostis brevifolio Benth.) in India.
193. (192) Leptochloa Beauv. (Oxydenicu Nutt., Rub(dochlor Beauv.). Inflorescence a panicle formed of numerons slender spikes; spikelets small, two- $\infty$-flowered, rarely one-flowered, compressed ; glumes and palea keeled; flowering glume obtuse or acute, rarely awned.

Species twelve, in the warmer countries of both hemispheres. One, L. mucronata Kunth, in temperate North America.
194. (193) Buchloë Engelm. (Bulbitis Rafinesque). Male plant with 2-4 short unilateral spikes, spikelets olituse,

2-3-flowered ; inflorescence of the of plant capitate, sessile (recalling Cenchrus), scarcely exserted from the sheath of the subtending leaf; empty glumes two, concave, indurated, three-lobed.

Species one ( $B$. ductyloides Engelm.), the renowned "Buffialo grass" of the North American prairies. In Texas it remains green over winter, and if it completely dries up during the summer drouth it is still readily eaten by cattle, and a few hours' rain is sufficient to make it green again.
195. (195) Opizia Pres1. of spikelets in several alternating, slender spikes; second empty glume of the of spikelet with three long awns surrounding the rest of the spikelet like an involucre; flowering glumes twolobed, sterile bracts long-awned.

Species one (O. stolonifera Presl), in Mexico.

## Tribe XI.-Festucee.

Inflorescence in panicles or racemes (apparently spikes on account of the very short pedicels of the spikelets) ; spikelets $2-\infty$-flowered, rarely one-flowered, usually $\stackrel{+}{c}$; empty glumes usually shorter than the nearest flowering glume; flowering glumes awnless or with from one to many awns which are usually terminal, rarely dorsal, and straight (very rarely geniculate) ; paleæ twokeeled; embryo usually small; starch-grains usually compound. The most important meadow-grasses of the temperate zones, as well as the predominating grasses of high mountains in the tropics.
A. Flowering glumes divided into three-to-many awn-like lobes, or with the awns rising from between the lobes, or dorsal.
a. Flowering glumes cleft above into 9-23 awn-like divisions. . . . . . . . 196. Pappophorum.
b. Flowering glumes with $9-11$ irregular, membranaceous, awned lobes. .
c. Flowering glumes with 5-9 dorsal awns.
269. Boissiera.
d. Flowering glumes with four membranaceous lobes, between and at the sides of which arise five awns.
198. Schmidtia.
e. Flowering glumes with five sharp, sulbulate divisions, which are bent backwards. Spikelets twoflowered; inflorescence capitate. . 206. Echinaria.
f. Flowering glumes with $3-5$ lanceolate, pointed, rigid, and erect or straight lobes. Spikelets manyflowered, in racemes. . . . . . 207. Orcuttia.
g. Flowering glumes with five delicate awns.
210. Sesleria, Sec. Psilathera.
h. Flowering glumes five-cleft, divisions awl-shaped, the middle and two outer ones awned.
199. Calamochloa.

Note.-Compare Trivaphis.
i. Flowering glumes deeply 3-4-cleft•with a dorsal awn. . . . . . . . . . 201. Pommoreulla.
k. Flowering glumes deeply four-cleft, usualiy awned between the hyaline divisions. 200. Cathestechum.

1. Flowering glumes of the fertile flower three-cleft, three-awned.
$\alpha$. Plant diocious, the two sexes very unlike.
2. Scleropogon.
ß. Plant hermaphrolite. . . . 203. Triraphis.
B. Flowering glumes entire or two-toothed to two-cleft, anmless or with one aun (3-5-awned only in a variety of Bromus macrostachys).
a. Rachilla or flowering glume (at least of the fertile flower) with long hairs which envelop the latter. Tall, reed-like grasses.
$\alpha$. Plant dioecious, \& spikelets hairy, \& spikelets naked.
3. Gynerium.
$\beta$. Plant hermaphrodite (very rarely diøecions), all the spikelets hairy.
I. Flowering glumes thick-membranaceons, five-nerved. . . . 215. Ampelodesmos.
II. Flowering glumes thin-membranacenus or hyaline, three-nerved.
$1^{\circ}$. Flowering glumes hairy, rachilla naked. 216. Arundo. $2^{\circ}$. Hairs on the rachilla only.
b. Rachilla and flowering glume naked or hairy; hairs much shorter than the glumes.
$\alpha$. Stigmas with short hairlets on all sides (barbellate), projecting from the point of the flowering glumes, upon elongated, free styles.
I. Spikelets diwecions, solitary, terminal, concealed between the leaves.
4. Monanthochloë,
II. Spikelets usually in threes, terminal in the axils of stiff, spinescent leaves which project far beyoud them. . . 205. Munroa.
III. Spikelets in a capitate panicle which is enclosed within the sheath of a bract-like leaf and falls off with it. 209. Urochlæna.
IV. Spikelets in a capitate or short cylindrical panicle which is neither surrounded by a leaf nor deciduous; the spikelets also (at least their empty glumes) persistent.
$1^{\circ}$. Lowest spikelet with bracts at the base.

* Empty glumes winged upon the keel; spikelets very many-flowered. 208. Ammochloa.
** Empty glumes not winged, spikelets 2-6-flowered. . 210. Sesleria.
$2^{\circ}$. Lowest spikelet without bracts at the base.

211. Oreochloa.
V. Spikelets in contracted, spike-like panicles, articulated below the empty glumes and falling off one by one.
212. Fingerhuthia.
VI. Spikelets minute in compact, very long, lobed panicles whose ultimate branches are subtended by subulate bracts ; spikelets minute, not decidnous.
213. Elytrophorus.

Note.-Compare Streptogyne, Zeugites, Schismus.
$\beta$. Stigmas plumose, relatively short, sessile or raised on a short style, emerging from the sides of the flowering glume.
I. Spikelets of two forms, the fertile 1-3-flowered, surrounded by the sterile consisting of many glumes.
$1^{\circ}$. Fertile spikelets one-flowered, sterile spikelet with obtuse glumes.
254. Lamarckia.
$2^{\circ}$. Fertile spikelets 2-3-flowered, sterile spikelet with awned or pointed glumes. 253. Cynosurus.
II. Spikelets all alike.
$1^{\circ}$. Flowering glumes thee-toothed, threepointed or two-toothed, usually threenerved; lateral nerves and the callus usually hairy.

* Spikelets with only one fertile flower, four empty glumes and one upper, empty, three-awned rudiment. . . . 218. Blepharidachne.
** Spikelets with three to many fertile flowers; empty glumes two.

219. Triodia.
*** Spikelets 1-3-flowered ; flowering glumes keeled; branches of the diffuse panicle very long and capillary. . . . . 219a. Redfieldia.
Note.-Compare 1)iplachne with its sharpkeeled flowering glumes.
$2^{\circ}$. Flowering glumes of some other structure.

* Flowering glumes 1-3-nerved, all with $\nsucc$ flowers, or the uppermost only with a f flower, or empty.
† Pauicle-branches spirally arranged.
O Panicle-branches in spikelike racemes either with short-pedicelled or sessile spikelets.
$\triangleleft$ Flowering glumes keeled.

220. Diplachne.
$\triangleleft \triangleleft$ Flowering glumes rounded on the back.
221. Ipnum.

O○ Branches of the panicle again with branchlets, these becoming shorter above.
$\triangleleft$ Spikelets loosely 2-4flowered, conical; rachilla articulated. 222. Molinia.
$\triangleleft \triangleleft$ Spikelets densely manyflowered; rachilla usually continuous: if articulated, the spikelet not conical.
223. Eragrostis.
$\dagger \dagger$ Primary panicle-brauches distichous, usually branched again at the base.
O Empty glumes much longer than the flowering glumes. 221. Dissanthelium.

00 Empty glumes not at all or only a little longer than the flowering glumes.
$\triangleleft$ Panicle spike-like or very much contracted, usually dense.
X Second empty glume much broader and somewhat longer than the flowering glumes.
$\square$ Flowering glumes broadly obtuse, awnless.
225. Eatonia. ㅁ․ Flowering glumes awned.
226. Avellinia.

XX Second empty glumes not broader nor longer than the flowering glumes. 227. Kœleria.
$\triangleleft \triangleleft$ Panicle diffuse, with long slender branches.

XX Empty glumes very unequal, lower almost wanting.
229. Sphenopus.
$\triangleleft \triangleleft \triangleleft$ Panicles with very short but spreading and somewhat stout branches. Glumes indurated.
230. Cutandia.
** Flowering glumes 3-5- to manynerved, with two or more of the upper glumes empty; appressed and frequently enclosing or enveloping each other.
$\dagger$ The sterile upper glumes forming together at their tips a tuft of awns.
O Leaves narrow-linear.
231. Ectrosia.

○○ Leaves broad-lanceolate.
240. Lophatherum.
$\dagger \dagger$ Sterile glumes not awned.
O Flowering glumes flabelliform, white-membranaceous, and corolla-like.
234. Anthochloa.

O○ Flowering glumes of some other form.
$\triangleleft$ Spikelets laterally compressed; glumes sharply keeled.
X Empty glumes persistent; flowering glumes 5 -nerved.
233. Heterachne. XX Spikelets deciduous as a whole; flowering glumes three-nerved.
232. Harpachne.
$\triangleleft \triangleleft$ Spikelets not at all or only slightly compressed ; glumes not keeled.
X Stamens three; lodicule one; upper sterile glumes usually clubshaped. . 235. Melica. XX Stamens 1-2; lodicules two; sterile glumes not clubshaped. 236. Diarrhena. Note.-Compare Streptogyne.

*** Flowering glumes five- to manynerved; each containing a $\stackrel{\text { flower, }}{\text { flo }}$ or the upper with only a of flower or empty (very rarely in many Festuca and Bromus species there are several empty glumes above the fertile; in Zeugites there are several $\delta$ flowers and only one | f |
| :---: | .

$\dagger$ Leaves broad, lanceolate or ovate, with fine transverse veins between the longitudinal nerves.
O Spikelets one-, rarely twoflowered.
$\triangleleft$ Spikelets in a long unilateral raceme; stigmas very long and spiral.
242. Streptogyne.
$\triangleleft \triangleleft$ Spikelets in several short spikes which are united in pairs along the axis of a panicle.
241. Pœcilostachys.
$\triangleleft \triangleleft \triangleleft$ Spikelets paniculate.
239. Orthoclada.

O○ Spikelets many-flowered.
$\triangleleft$ All the flowers $\psi$.
237. Cenototheca.
$\triangleleft \triangleleft$ Only the lowest flower $\wp$, the others $\hat{\delta}$, remote.
238. Zeugites.
$\dagger \dagger$ Leaves linear or lanceolate, no distinct transverse veins.
O Keel of the palea winged or with a linear appendage.
243. Pleuropogon.

OO Keel of the palea not appendaged.
$\triangleleft$ Empty glumes 3-6 at the base of each spikelet. X Spikelets one-flowered. 244. Brylkinia. XX Spikelets many-flowered. . . 245. Uniola.
$\triangleleft \triangleleft$ Empty glumes two. $X$ Plants strictly diœcious; spikelets almost sessile. 246. Distichlis.
XX Plants hermaphrodite (very rarely diœcious, and then loosely paniculate).
ㅁ Flowering glumes cordate at the base. 247. Briza. $\square \square$ Flowering glumes not cordate at the base. . . AA, etc.
AA. Spikelets closely imbricate, arranged in a linear, dense, false spike.
aa. Flowering glumes lanceolate, indistinctly fivenerved. . . . . . . . 249. Wangenheimia.
bb. Flowering glumes broadly ovate-lanceolate, seven-nerved with glandular hairs at the base.
248. Desmazeria.

Note.-Compare Festuca and Brachyporlium, whose spikelets stand farther apart and whose glumes are not keeled.
BB. Spikelets densely imbricate, crowded in short spikes,
several of which are united into a raceme or form a capitate inflorescence.
250. 居luropus.
CC. Spikelets in small fuscicles which are united into a glomerate or interrupted panicle.
aa. Panicles one-sided. . . . . . 252. Dactylis.
bb. Pauicles symmetrical. . . . 251. Lasiochloa.
DD. Spikelets in panicles or racemes, neither imbricated nor in fascicles.
aa. Branches of the panicles in at least twelrerayed false whorls, the lowest of which is sterile. . . . . . . . 257. Nephelochloa. Note.-Compare Poa, Sec. A.
bb. Branches of the panicles in whorls of $1-5$. $\alpha \alpha$. Stigmas two, inserted at or near the apex of the ovary ; empty glumes awnless.

* Empty glumes longer than all the flowering glumes.
$\dagger$ Flowering glumes two-cleft or twolobed. . . . . . 256. Schismus. $\dagger \dagger$ Flowering glumes entire, or finely toothed. . . . . 260. Dupontia.
** Flowering glumes, at least of the uppermost flowers, projecting from the empty glumes.
$\dagger$ Lateral nerves of the floral glumes nearly parallel, not converging.
O Empty glumes but little or not at all shorter than the nearest flowering glumes.
$\triangleleft$ Flowering glumes with two very short, nearly obsolete, nerves on each side.

259. Colpodium. O○ Flowering glumes with 3-4 nerves on each side, at least one of which is prolonged beyond the point.
260. Scolochloa.
$\triangleleft \triangleleft$ Empty glumes much shorter than the nearest flowering glume.
$\triangleleft$ Styles distinct, lodicules grown together.
261. Glyceria.
$\triangleleft \triangleleft$ Styles none, lodicules distinct. . . . 264. Atropis. $\dagger \dagger$ Lateral nerves of the flowering glumes arched, converging above toward the mid-vein.
O Rachilla with a fringe of stiff hairs. . . 262. Graphephorum.
OO Rachilla naked, downy, or with flexuose (or webby) hairs.
$\triangleleft$ Flowering glumes strongly keeled on the back; hilum punctiform.
X Flowering glumes cartilaginous at the base, upper half herbaceous.
262. Sclerochloa. XX Flowering glumes membranaceous or herbaceous at the base. . . 258. Poa.
$\triangleleft \triangleleft$ Flowering glumes rounded on the back, at least below. $X$ Palea rough or minutely fringed upon the keels.

- Hilum linear.

265. Festuca.
$\square$ Hilum punctiform.
§ Spikelets in a simple or brauched raceme.
266. Catapodium.
§§ Spikelets in a shortbranched panicle.
267. Scleropoa.

XX Palea pectinately fringed on the keels.
271. Brachypodium.
$\beta \beta$. Stigmas two, plainly arising below the apex (lateral) on the anterior portion of the ovary ; empty glumes awnless.
> $\gamma \gamma$. Stigmas three, inserted at the aper of the ovary (terminal); empty glumes extending into long awns.
> 270. Megalachne.

## Sub-tribe A.-Pappophoreæ.

Flowering glumes with three to many awns or lobes.
196. (197) Pappophorum (Fig. 72). Panicles spikelike. Sjikelets 1-3-Howered. At maturity the Howering glumes with their numerous awns resemble the fruit of a Composite with pappus.

Species about twenty, especially in the tropics of both hemispheres, one extending as far as Northern Asia, North America, and Australia.

Sec. I. Polyraphis Lindl. (as a genus). Flowering glumes with 13-23 naked awns.

Sec. II. Enneapogon Desv. (as a genus). Flowering glumes with nine, usually plumose, awns.
197. (198) Cottea Kunth. Panicles loose ; spikelets. 2-6-llowered, broad, short-a wned, laterally compressed.

Species one (C. pappophoroides Kunth), in tropical America as far
 north as Arizona and New Mexico. Fig. Ta-Papponhmem palli-
198. (200) Schmidtia Stend. An- dum Brown. After Kunth, toschmirltiu Steud.). Panicles narrow, loose; spikelets resembling those of a small Avena; empty glumes long.

Species two, from tropical South Africa to Egypt.
199. (208) Calamochloa Fournier. Tnflorescence an orate panicle composed of short spikes. Spikelets 3-4 in each spike, two-flowered. Flowering glumes hairy on the callus.

Species one (C. filifolia), in Mexico.
200. (62) Cathestechum Presl. Spikelets in groups of threes, these in loose rows on a common axis and decidu-
ous as a whole ; middle spikelet $2-1$-flowered, the lateral 1-2-flowered.

Species two, one ( C. prostratum Presl), in Mexico, and one ( $C$. erectum Vasey d Hack.) in Texas and Sonora.
201. (196) Pommereulla L. fil. Spikelets sub-turl, inate, in a dense spike, sheathed at the base. Flowering glumes finally inturated and with a pointed callus. A small, anuual grass.

Species one ( $P$. Cornucopire L. fil.), in the East Indian Peninsula.
202. (204) Scleropogon Philippi (Lesourdia Fourn.). Inflorescence an almost spike-like panicle at whose apex there is, in the of plant, a tuft of sterile spikelets (each reduced to a single glume); of plant with awnless or shortly three-toothed flowering glumes.

Species three (?), one in Chili which, together with one or two others, extends into Mexico and Texas.
203. (206) Triraphis Brown. Panicle narrow, elongated, with upright many-flowered spikelets; flowering glumes sometimes with membranaceous marginal lobes. Grasses with narrow or rush-like leaves.

Species five in Anstralia, one in South Africa.

## Sub-tribe B.-Seslerieæ.

Flowering glumes 1-5-awned, lobed, or awnless; style and stigma usually long, the latter narrow, protruding near the apex of the thowering glume.
204. (213) Monanthochloë Engelmann (Hutochlore Griseb.). A creeping grass of the sea-coast and alkaline plains, with crowded, short, convolnte leaves and nearly concealed spikelets.

Species one (M. littoralis), from Florida to California, and represented by a variety in the Argentive Republic.
205. (214) Munroa Torrey. Low grasses of the elerated plains. Brauches much forked or fasciculate; leaves cuspidate-pointed, in clusters at the ends of the branches; spikelets nearly concealed by the upper leaves.

Species three, one ( $\boldsymbol{M}$. squarrosa Torr.) on the plateanx of the Western United States and the Argentine Republic, two in extra-tropical South America.
206. (215) Echinaria Desf. (Panicustrella Münch.). A low amnual. Spikelets in long-perlicellate, spiny, capitate clusters ; 2-3-flowered.

Species one (E. capitatu Desf.) (Fig. 73), in the Mediterranean regions.
207. Orcuttia Vasey. A low, prostrate ammal, with long spikelets in racemes; empty glumes much like the
 flowering glumes, lobed.

Species one ( $O$. Californica Vasey) (Fig. 73a), in Lower California (San Quentin Bay). 208. (216) Ammochloa Boiss. (Cephalochloa Cosson \& Dur.). Spikelets small, in globose,

Fig. 73.-Echinaria capitata Desf. (After Nees, Gen. Germ., I. 38.)

[Fig. 73a.-Orcuttia Californica Vasey. A, Portion of inflorescence. El, Floret with a portion of the rachilla. $D$, Dorsal view of expanded flowering glume. $E$, Aper of palea. $S t$, Stamen. J. Pistil. (Original.)]
capitate clusters, many-flowered ; flowering glumes threenerved with a rigid or cuspidate point.

Species two ; low, ammual, steppe aud desert grasses: A. pungens Boiss. in Algiers ; A. subucaulis from Algiers to Palestine and South Spain.
209. (217) Urochlæna Nees. Spikelets few-flowered; glumes 5-7-nerved and produced into long, divergent and curved awns.

Species one (I. pusillu Nees), in South Africa. A low, branched annual.
210. (218) Sesleria Scopoli (Fig. 74). Ghumes keelect,
 membranaceous ; flowering glumes with $3-5$ small teeth that are frequently produced into short awns. Panicles very dense and spike-like or capitate. Perennial grasses.

Species ten, in Europe and Westorn Asia, mostly alpine. $S$. corulea Ard., with 3-5 short awns, extends all through Europe. Psilathera Link (as a genus) is a species (section?) with five distinct awns on the flowering glume and two short awns on the palea.
211. (223) Oreochloa Link. Habit of the preceding, but with no bracts at the base of the spike. Spikelets two-ranked, turned to one side.

Species two, O. disticha Lk. from the Carpathians to the Pyrenees, and O. Pedemontana Boiss. \& Reut. in the W. Alps and Castile.
212. (220) Fingerhuthia Nees. Habit of Seslerid; the uppermost and lowest spikelet of the false spike aborted. A \& flower, or empty glame with a short awn, above the $\%$ flower.

Species one ( $F$. Africtonct Lehm.), in South Africa ant Arghanistan.
213. (219) Elytrophorus Beanv. Spikelets minute, in small capitate clusters and these mited into a long contracted panicle which appears like a small brush on arcoment of the numerous, short awns. Spikelets manyflowered, with only one posterior stamen.

Species one ( $\boldsymbol{E}$. articulutus Beaus.), extending through the entire tropical zone of the Old World.

## Sub-tribe C.-Arundineæ.

Flowering glumes awnless or short-awned; rachilla or flowering glume with long hairs.
214. (209) Gynerium Humb. \& Bonpl. Spikelets loosely 2 - $\infty$-flowered, narrow ; glumes membranaceons ; flowering glume three-nerved, subulate, produced into a

Fig. $75 .-G y n e r n m$ argenterm Nees. (From Müller's "Die PHanzenwelt.")
fine awn. Tall reed-like grasses with long, rigid, narrow leaves that are much crowded at the base, and very large, thick, silvery-shining panicles.

Species three, in tropical and sulb-tropical America. G. argenterm Nees, "Pampas-grass," from Southern Brazil and the Argentine Republic, has a culm $3-6 \mathrm{~m}$. high; leaves $1-3 \mathrm{~m}$. long ; panicles $0.5-0.8 \mathrm{~m}$. long; the 3 panicle broad-pyramidal; the of narrower, linear, elongated,
with a magnificent silvery-white or rose-red sheen. Showy, decorative plants for the garden. The panicles are used for dry bouquets. [Growing Pampas-plumes is an important industry in California. The plumes are cat when exposed only a few inches from the leaf-sheath.] In its native habitat the leaves are used for paper-making, and a decoction of the rhizome is employed as a diuretic.
215. (210) Ampelodesmos Beauv. Spikelets crowiled, $2-\infty$-flowered ; flowering glumes and the short joints of rachilla clothed with short, woolly hairs; flowering glumes with two short teeth between which is a cuspidate point ; ovary hairy above.

Species one (A.tenax Link). A low, cane-like grass with nodding pauicles and rush-like leaves, in the regions of the Mediterranean, and especially abmetant in Algiers. The young leaves are used for forlder, and the very tough old ones are employed like Esparto ; in Italy

Fig. \%6.-Arundo Domux L. After Nees, hats are woven from them, and in Sicily they are used to tie up grapes.
216. (211) Arundo L. (Donax Beauv., Amphidonax Nees, Scolochloa Mert. \& Koch). Spikelets crowded with many flowers ; rachilla naked; flowering glumes with long hairs, 2 -toothed and a cuspidate point between the teeth; ovary naked. Tall reed-like grasses with almost woody stems and broad flat leaves.

Species six, distributed throughout the warmer countries of the world. $A$. Donax L. (Fig. 76) has a culm 2-4 m. high and fully Gen. (ierm.. I. 36.) 2 cm. thick below. Grows wild in wet places in the Mediterranean region, and is
generally cultivated in Spanish South America, forming living fences. The culms are used for laths, and, wheu split, for woven work. The leaves are used for roofing, aud the rhizomes are employed as a diuretic. It is also grown as a decorative plant. [There is a cultivated variety which has its broad leaves striped with longitudinal white bands.]

Fossil Species.-Many rhizomes, culms, and leaves of A. Goepperti Heer are found in the tertiary of Europe and N. America which show points of agreement with the living species. A. Groentandicu Heer occurs in the upper chalk formation of Greenland.
217. (212) Phragmites Trin. (Czernya Presl). Spikelets loosely many-flowered, lowermost flower $\hat{f}$, the others usually $\ngtr$; rarely the plants are diocious, but without any striking distinction between the sexes; fiowering glmmes naked, long-acuminate-pointerl. Habit of Aruudo, but with the culm usually not so stout.

Species three, one cosmopolitan, a second in tropical Asia, and a third (diocious) in the Argentine Republic. $P$. communis Trin. is a reed-like grass with culms $1-3 \mathrm{~m}$. high and expanded, usually purple or violet colored panicles. It grows in standing or sluggish water and in swamps, is gregarious in liabit, and is distributed throughout the world. The culms are used for roofing and as laths for covering walls about to be plastered, for matting, basket-work, mouth-pieces of musical instruments, weavers' spools, etc.; the young shoots are fed to horses, and an infusion of the root is used as a diuretic.

Fossil Species.-Ph. Ungeri Stur. Rhizomes in the lacustrine strata in Hungary. Ph. oeningensis A. Br. is found in the tertiary of Europe, the polar regions and N. America. Ph. cretaceus Lesq. in the cretaceous formation of N. America.

## Stb-tribe D.-Triodieæ.

Flowering glume usually 2 - 3 -toothed; middle tonth often awned or awn-like.
218. (205) Blepharidachne Hack. in Monogr. Androp.,

1. 261 (Eremochlö̈ S. Wats.). Low, branched grasses, with crowded, involute leaves; spikes few, in capitate panicles; flowering glumes very hairy.

Species two, upon the high western plateaux of North America.
219. (201) Triodia Brown. Panicle usually open; flowering glume rounded on the back (at least below),

Fig. 7 IT.-Triodia decumbens Beauv. After Nees, Gen. Germ., I. 51.) coriaceous or chartaceous, often hairy on the callus and margins. Perennial grasses with narrow rigid leaves and variable habit.

Species twenty-six, throughout the temperate zones, a few in tropical America.

Sec. I. Isotria. Flowering glume three-parted almost to the middle. Tr. pungens Brown, and the related Tr. Mitchelli, Tr. Cunninghamii, and Tr. irritans Brown, belonging to the following Sec., are characterized by their rigid, involute, finelypointed, and often sticky leaves; they cover, often exclusively, large areas of the deserts and elevated plains of the interior of Australia, and are known to the colonists and to travellers as "Spinifex" (not to be confounded with No. 76), and are very troublesome.
Sec. II. Sieglingia Bernhardi (as a genus). Flowering glume with three short, rather obtuse teeth. Triodia decumbens Beauv. (Fig. 77) in Europe.

Sec. III. Rhombolytrum Link (as a geuns). Flowering glume shortly two-toother, sometimes entire. In North and South America. (T. filiformis Nees, T. clbescens Munro, etc.)

Sec. IV. Tricuspis Beauv. (as a genus), (Windsorin Nutt., Tridens R. de S.). Flowering glume usually entire, but with the three nerves extending into three short awn
or sharp points. T. cuprea Jacq., a showy grass with open panicles [common in the Eastern United States].

Sec. V. Triplasis Beaur. (as a genus), (Uralepis Nutt., Diplocea Raf.). Flowering ghmes three-cleft, the middle division recurved and awn-like. North America.

219a. Redfieldia Vasey. Florets crowded, the short joints of the rachilla smooth. Flowering glumes chartaceous, densely hairy on the callus only, 3 -nerved, indistinctly 3 -toothed or terminating in a shortmucronate point. Styles long ; stigmas short. Grain oblong, terete, free.

Species one (R. Alexuosa Vasey, Graphephorum (?) flexuosum Thurber), (Fig. 78) in the Western United States.

220. (202) Diplachne Beaur. Fic. r8.-Redfieldia flexuose Tasey. Spikelets narrow, manyflowered; flowering glumes 1-nerved, keeled, usually
$B$, Spikelet. $a$, A single Horet show. ing joint of rachilla, etc. $\quad a^{\prime}$, A single Horet from a one-flowered spikelet, with a rudiment of a second floret. above. $b$, Apex of flowering glume. $E$, Palea. $F$, Flower. (Original.) 2 -toothed, the teeth mucronate or awn-pointed ; fruit 3 -angled, unfurrowed.

Species fifteen, in the warmer countries of both hemispheres. Leptocarydion Hochst. and Trichoneura Andersson include species that form a transition to Triodio.

## Sub-tribe E.-Eragrosteæ.

Flowering glumes three nerved, awn less or short-awned.
221. (226) Dissanthelium Trin. (Phularidium Nees, Stenochloa Nutt.). Panicle narrow; flowering glumes hroad, obtuse, awnless, 3-nerved, the lateral nerves nearly marginal.

Species three, of low habit, one in California, the others upon the Andes of South America and coasts of Mexico.
222. (227) Molinia Schrank (Enodium Gaud.). Pani
cles diffuse or contracted; spikelets narrow, pointed, awnless. Peremial grasses with apparently noteless culms.

Slpecies one (M. cormed Mönch), with violet-colorect panicles and rigid leares, grows in wet meadows in Central Enrope and temperate Asia. A poor grass for forder. [Sparingly introduced into North America.]
223. (230) - Eragrostis Host. (Fig.

Fig a9.-Ercurrostisminor.
Host. $R$, Rachilla with paleæ. (After Nees, Gen. Germ., I, 55, and 79). Panicles various, generally open. Spikelets usually densely manyHowered ; flowering glumes awnless, or at most mucronate-pointed, keeled; grain globose or ovate, unfurrowed.

Species about one handred, distributed throughout all warm countries.

Sec. I. Cataclastos. Racbilla articulate ; spikelets small ; flowering glumes membranaceous. E. ciliaris Link in the Southern United States and throughout all tropical countries. Macroblepharus Philippi also belongs here.

Sec. II. Petroëssa (Megastachya Beauv.). Rachilla and usually also the paleæ remaining after the frnit and flowering glumes have fallen. Most of the species belong here. E. Abyssinice Link, is an important food-plant in Abyssinia. The various colored seeds have the appearance of grits, and the flour made from these is baked into bread. This grass is probably a cultivated form of $E$. pilose Beaur. Many species (e.g., E. Mexicuna Link) are cultirated for ornament. [E. orylepis of the Southwestern Uuited States, is a particularly showy species.]

Sec. III. Myriostuchya. Like the precerling, but with long-awned empty glumes.

Species one.
Sec. IV. Plutystachyu. Rachilla articulate; spikelets large; flowering glumes coriaceous.
224. (231) Ipnum Philippi. Spikes short, standing
almost at right angles to the common axis; spikelets cylindrical; flowering glumes with a short mucronate point.

Species one (I. Mendocinum Phil.), in the Argentine Republic.

Obs. -This genus most probably belongs to Diplachne.

225. (225) Eatonia Raf. (Reborler Kunth, Colobrmthus Trin.). Spikelets two-flowered, small, shining, very numerous in contracted [expanded in flower] and ofteu dense panicle. Habit of Koeleria.

Species two, E. oltusa and E. Pemsylvanica Gray, in North America [probably a third species is represented by E. filiformis Vasey].
226. (224) Avellinia Parl. A small, annual grass with a slender pauicle, and very narrow spikelets; lowor empty glumes short, rery narrow, almost setiform, the second very large; flowering glumes awned below the point.

Species one ( $A$. Michelii Parl.), in the regions of the Mediterranean.
227. (223) Kœleria Pers. (Collinaria Ehrh.). Spikelets 2-5-flowered, shining; empty glumes unequal; flowering glumes keeled, entire, awnless, or shortawned. Usually low, narrow-leaved grasses, with narrow, compact panicles.

Species fifteen, distributed throughout the temperate regions, mostly in Europe; isolated species in South Africa, Patagonia, and the Sandwich Islands.

Sec. I. Airochloa Link (as a genus). Flowering glumes awnless or with short mucronate points. K. cristata Pers., with silvery shining panicles; upon dry meadows in Europe and Western North America. A profitable fodder-grass for sandy soils.

Fig. 80. - Keleria phlenites Pers. Ifter Nees, Gen. Germ., I. 63.)

Sec. II. Lophochor Reichen. (as a gemus), (Agiulitis Trin., Egialina Schult., Willelmsia C. Koch). Flowering grlumes short-awned from or below the point. $K$.
phleoides Pers., in the regions of the Mediterranean (Fig. 80).
228. (229) Catabrosa Beauv. Spikelets small ; twoflowered; empty ghumes almost nerveless and rery ohtuse, much shorter than the awnless, indistinctly three-tonthed flowering glume. Creeping, aquatic grasses with open pyramidal panicles.

Species one ( C'. aquaticu Beanv.), in Europe, Northern Asia, and North America.
229. (228) Sphenopus Trin. Small, delicate, ammal grasses with minute awnless spikelets upon somewhat thickened perlicels. Branches of the panicle in fascicles, finally spreading.

Species one (Sph. Gouani Trin.), along the shores of the Mediterranean to the Caspian Sea.
230. (232) Cutandia Willk. Panicles few-flowered, the short branchlets thickened at the point and finally strongly divaricate; spikelets narrow, lonsely flowered, usually awnless. Amual, low, maritime grasses.

Species six, in the Mediterranean region. C. maritima Benth. on the seashore.

## Stb-tribe E.-Meliceæ.

Uppermost glumes of the spikelets empty (rarely with flowers), overlapping or embracing each other.
231. (234) Ectrosia Brown. Panicles many-flowered, narrow, compound; spikelets with 1-2 fertile, shortawned flowers, followed by 1-2 \& flowers and several sterile glumes.

Species four, in Australia. E. leporina Brown, in North Australia and Queensland.
232. (230) Harpachne Hochst. Spikelets in a simple raceme with spirally arranged branches which finally fall off and bore into objects by means of their pointed, hairy bases; : $3-4$ fertile flowers and two sterile lougpointed glumes.

Species one ( $H$. Schimperi Hochst.), in tropical Africa.
233. (235) Heterachne Benth. Spikelets rery flat, in false spikes or heads, with one fertile flower and (6-14
empty glumes which form, as it were, an appendage to the fruiting glume; flowering glumes awnless.

Species two, H. Broumii and M. Gulliveri Benth., in North Australia.
234. (236) Anthochloa Nees. Panicles capitate, small ; spikelets few-flowered, awnless; flowering gilumes broat, flabellate, finely toothed, thin-membranaceous, silvery white.

Species two, in the Audes of Peru and Bolivia. The small heals of $A$. lepida recall those of Helichrysum or Paronychia.
235. (237) Melica L. Spikelets few-flowered, mostly in narrow or spike-like panicles; empty glumes membranaceous, 3-5-nerved; flowering glumes parchment-like, mostly 7-9-nerved, awnless or short-awned; anterior lodicules entire or slightly emarginate.

Species over thirty, throughout temperate zones, excepting in Australia. M. nutans (Fig. 81), a forest grass in Europe, has narrow panicles and nodding, naked spikelets; M. ciliata L. has eylindrical ${ }_{\text {Fig. }}$ 81.-Melica mutans L . (After false spikes, and long-fringed

Nees, Gen. Germ., I. 60.) flowering glumes. It grows upon sumy hillsides in Europe, also cultivated for ornament.
236. (238) Diarrhena Rafin. (Korycorpus Zea, Romerin Zea, Onoen Framehet and Saratier). Spikelets in a loose panicle, 3 -5-flowered, almost linear; flowering glumes coriaceons, shining, three-nprved, awnless; fruiting glumes somewhat remote, spreading, learing the heaked caryopsis exposed.

Species two, one (D. Joponict Franch. and Sav.) in Japan and one (D. Americrma, P. B.) in North America.

## Sub-tribe F.-Centotheceæ.

Leaves broad, netted-veined.
237. (239) Centotheca Desv. Panicles expanded; spikelets small; flowering glumes rounded on the back, 5)-7-nerved, awnless, but usually with hooked appeudages or small protuberances on the keel.

Species three, in tropical Africa, Asia, and especially the South Sea Islands.

2:38. (243) Zeugites Schrel. (Senites Adans., Despretzic Kunth, Kromblholzin Fourn.). Spikelets panicled, manyflowered, bat only the lowest fertile, the very broad empty glumes approximate ; the upper of, distant; leaves ovate.

Species five, in tropical America and Mexico.
239. (240) Orthoclada Beauv. Panicles diffiuse ; spikelets lanceolate, compressed, one-flowered, with a long prolongation of the rachilla (rarely two-flowered without this prolongation) ; fruit strongly compressed laterally.

Species one (O. rariflora Beauv.), with petiolate, broad lanceolate leaves ; in tropical America.
240. (241) Lophatherum Brongn. (Acroelytrum Stenct. and Alletotheca Steud.). Spikelets often two-ranked (rarely scattered), sessile on the branches of the panicle, linear, one-flowered, with a tuft of sterile glumes at the point. Empty glumes two; flowering glumes pointed or short-a wned.

Species three, in the East Indies in the Sunda Archipelago to Japan.
241. Pœcilostachys Hackel. Spikelets in pairs on the spike-like branches of the panicle ; empty glumes three, $n o$ sterile glumes at apex. A sterile flower is often found in the axil of the third glume.

Species two, P. Hildelrandtii and $P$. geminate Hack., in Madagascar.
242. (242) Streptogyne Beauv. Spikelets large, linear, almost sessile; first empty glume short, the second as well as the flowering glume involute, many-nerved, the latter short-awned, and with 1-.3 empty falcate glumes ahore it.

Species one (St. crinito Link), in the tropies of both hemispheres. The detacher truiting glumes hang for a
long time ly the spiral styles and stigmas which are jure terlaced above.

Sub-tribe G.-Eufestuceæ.

Without the special characteristics of the preceding sulx-trihes. Flowering glumes five- to many-nerved.
243. (244) Pleuropogon Brown (Lophochrena Nees). Spikelets rather large in a simple, lonse raceme, 8-14flowered; flowering glumes 7 -nerved, mucronate-pointed or awned.

Species three, one ( $P$. Sulini Brown) arctic-circumpolar, and two in California.
244. (245) Brylkinia F. Schmidt. Inflorescence like the preceding; spikelets pendent, one-flowered with four empty glumes; flowering glumes long-awned. A weak, broad-leaved grass.

Species one ( $B$. coucluta F. Schm.), in Japan and Saghalin.
245. (246) Uniola L. (Trisiola Rafin., C'hesmentlium Link). Panicles usually loose, often showy; spikelets laterally compressed, broad, with 3-20 flowering glumes and 3-6 empty glumes. Flowering glumes chartaceous or coriaceous, with many delicate nerves.

Species five, mostly in North America; one in Central America; one in the Audes and extra-tropical South America. U. Tutifolic L. (Fig. 82), with broad leaves and elegant nodding spikelets, is a farorite ornamental grass.
246. (247) Distichlis Rafinesque. Spikelets 8-16flowered; the \& with a continuons and the of with an articulated rachis, oblong compressed; glumes and paleæ keeled, coriacenns ; flowering glumes many-nerved, acute, awnless, closely two-ranked. Creeping grasses with rigicl, densely two-ranked, involute leaves.

Species four, along the seacoast and on alkaline plains in the interior thronghout America, one of which, D. maritima, occurs also in Australia.
247. (253) Briza L. (Fig. 83). Spikelets many-flowered, panicled, broad ; glumes thin-membranaceous, very concare, densely crowded, five-to many-nerved; palea much
shorter than the flowering glumes. Fruit strongly dorsally compressed.

Species twelve, Europe, North Africa, and the temperate parts of Asia and South America.

Sec. I. Eubriza. Flowering glumes obtuse, without lateral projections, nerves separate their entire length. B. mediu L., "(uaking-grass," peremuial ; spikelets roundish. A valuable meadow-grass in Middle Europe. $B$. muxime L. has large ovate and $B$. minor L. small, three-

cornered, ovate spikelets; both wre ammals, and frequently cultivated as ormamental grasses for dry bouquets.

Sec. II. Chuscolytrom Desv. (as a genus). Flowering glumes awnlesis or mucronate-pointed, its nerves miting at the apex. B. erecta Lam., an ornamental grass.

Sec. III. Culothecu Desv. (as a gemus). Flowering glumes, with projecting lateral angles, awned.

Sec. II. \& III. In South America; B. eleguns Döll. in Uruguay.
248. (251) Desmazeria Dumort. (Brizopyrum Link).

Spikelets very many-flowered, strongly compressed, with crowded, two-ranked, coriaceous, sharply keeled glumes and paleæ. Flowering glumes pointed, awnless.

Species four, one in the regions of the Mediterranean, three in South Africa. D. sicula Dum. (Brizopyrum siculum Link) is an annual frequently cultivated as an ornamental grass.
249. (187) Wangenheimia Mönch. A small aunual grass, with very short, compact, and one-sided spikes. Spikelets awnless, sharply keeled, downy.

Species one ( $W$. distichu Mönch), in Spain and North Africa.
250. (248) Eluropus Trin. (Chumredactylis Nees). Creeping, rigid, much-branched grasses, with closely tworankerl, often stiff leaves. Spikelets densely crowded, many-flowered; flowering glumes 7-9-nerved, broad, somewhat mucronate-pointed.

Species four, mostly in the saline or alkaline soil in the regions of the Mediterranean, in Central Asia, Arabia, Hindostan.
251. (250) Lasiochloa Kunth. Spikelets 2-3-flowered in a crowded cylindrical or interrupted panicle. Empty glumes as long as the spikelet, 5-7-nerved, obtusely keelerl, tuberculate-hispid; flowering glimes awnless.

Species 3-4, in South Africa. L. hirto and L. rdscendens Kunth are the most frequent.
252. (249) Dactylis L. Spikelets 3-5-flowered, much compressed, somewhat concave on the inner side ; arrauged in dense fascicles; empty glumes $1-3$-uerved, as well as the flowering glumes, sharply keeled ; the flowering glumes fringed on the keel and short awn-pointerl.

Species one, with several varieties, throughout Enrope, in temperate Asia and North Africa. Naturalized in North America. D.glomerata L. (Fig. 84). Panicle made up of fascicles or dense glomerules. A first-class fodder-grass especially for heavy, wet soils. Very productive, rapidly growing, especially after cutting ; endures shade, and on this account is called "Orchard-grass" in North America.
253. (222) Cynosurus L. Panicles spike-like or capitate, one-sided; the fertile spikelets not enclosed by the pectinate sterile ones; flowering glumes awned from or below the point, or simply mucronate; glumes of the sterile spikelets 2 -ranked, spreading.

Species five, in the temperate zone of the Old World; one ( C. cristatus) has also been introduced into America.

Sec. I. Eucynosurus. Flowering glumes and sterile glumes mucronate-pointed, not awned. C. cristatus L.

Fig. 84-Dactylis glomerata L. (After Nees, Gen. Germ., I. 65.) (Panicle represented too loose.)

Fig. 85.-Cynosurus echinatus L. (After Mart. and Eichler, Fl. Bras, II, III, pl. 3\%) B.f., Fertile, B.s., sterile spikelets.
with linear false spikes, in all Europe on meadows. A good, tender fodder-grass, also good for the foundation of grass-plots or lawns.

Sec. II. Phrilona (Fralonri) Adans. (as a genus). Glumes awned. C. echinatus L. (Fig. 85) in South Europe, a field weed.
254. (221) Lamarckia Mönch. (Chrysurus Pers., Pterium Desv., Tincea Garzia). A low annual grass, with an elegant, one-sided, crowded panicle whose branches are terminated by the fertile spikelets, which are entirely covered up by the long awns of the sterile ones.

Species one ( $L$. aurea Mönch), in the regions of the Mediterranean to Afghanistan. Introduced in North America (California). A favorite ornamental grass ("Chrysurus cynosuroides").
255. (252) Sclerochloa Beauv. A prostrate, annual grass with short, one-sided, rigid panicles ; joints of the rachilla much thickened; glumes narrow, very obtuse.

Species one ( $S$. dura Beaur.), in southern and central Europe, western and central Asia.
256. (254) Schismus Beauv. (Electra Panzer, Hemisacris Steud.). Low, annual grasses with somewhat dense panicles. Large, somewhat acute, white, membrana-ceous-margined empty glumes; and small, membranaceous, $5-9$-nerved flowering glumes.

Species four, two South African, two from the Mediterranean to Afghanistan.
257. (255) Nephelochloa Boiss. Panicles very delicate; spikelets very small; flowering glumes with a straight awn projecting from the two-toothed point.

Species one ( $N$. orientalis Boiss.), in the Orient.
258. (256) Poa L. Spikelets 2-6-flowered, usually in open, rarely in spike-like panicles; rachilla and callus, as well as the marginal nerves of the flowering glumes, often clothed with tangled hairs; glumes herbaceous or membranaceous, awnless; flowering glumes often obtuse.

Species about one hundred, distributed throughout all temperate and cold countries; a few in the high mountains of the tropics; some cosmopolitan.

Sec. I. Pseudopoa. Habit of the preceding geuns. Fruit grown to the glumes, slightly furrowed.

Species three, P. Persica Trin. in Asia Minor and Persia.

Sec. II. Eupor. Fruit unfurrowed, mostly free. This section comprises some of the most important fodder-
grasses. P. pratensis L., "June grass," "Kentucky Blue grass" (Fig. 86), has underground

Fig. S6.-Poa pratensis L. $D_{1}$, Fruiting bract in eross-section. (After Nees, Gen. Germ., I. 56.) runners, smooth sheaths, and a short ligule. $P$. trivialis L. has aerial runners, rough sheaths, and a long ligule. $P$. alpina L. has no runners, its leaves are obtuse and spikelets large ; found in the high mountains of the northern hemisphere and in the Arctic region. The largest species of the genus is P. flabellata Hook. (Dactylis caspitosa Forst.) the "Tussock grass" of the Falkland, Fire Islands, and Kerguelen Land. This grass forms great tufts which reach 2 m . in height, and its leaves are arranged like a fan. Its culture is remunerative ouly where the summers are very moist.

Sec. III. Dioicopoa. Diocious, but without any other difference between the two sexes. Natives in America. $P$. Clrilensis Trin., P. lanuginosa Poir. (Poidium Nees is a scantily-flowered $P o a$ ).
259. (257) Colopodium Trin. (Arctoplita Rupr.). Spikelets 1 -2-flowered, loosely panicled; rather small and bright-colored. Flowering glumes broad, very obtuse, membranaceons, awnless; ovary naked. Habit of Porr.

Species twelve, in the Orient and contral Asia, especially on high momtains; two species ( C. fulloum and C . pendulinum (tris.) are arctic, forming a peculiar section (Avctoplitic) with the callus of the flowering glume hairy.
260. ( $258 \$$ ) Dupontia Brown. Differs from the precerting geums only in the longer empty glumes. Callus of the flowering glumes distinctly hairy ; panicles contracted.

Species two, D. Fischeri Brown and D. psilosemtlen Rupr., in the arctic zone.
261. ( 258 ) Scolochloa Link. Spikelets 3-4-flowered, lanceolate ; panicles loose ; flowering glumes rigid, not keeled, callus hairy ; ovary hairy. Tall, reed-like grasses.

Species two, in the northern temperate zones of the

Old and New World. S. festucacer Link in both Old and New World ; S. spiculose Schmidt only upon Saghalin.
262. (258) Graphephorum Desv. Like the precerling, but lower and more delicate in habit, with more delicate almost membranaceous glumes and naked ovary.

Species one (G. melicoides Desv.), N. America.
263. (259) Glyceria Brown. Spikelets many-flowered in narrow or expanded panicles. Flowering glumes rounded on the back, obtuse, awnless, somewhat dry-membranaceous near the tip ; 5-9-nerved. Fruit free, oval.

Species sixteen, mostly in N. America, some endemic in Australia, a few in Europe and Asia; one species, G. fluitans Brown, "Floating Manna-grass" (Fig. 87), which has linear, long-cylindrical spikelets, somewhat acute flowering glumes and narrow panicles, is cosmopolitan and aquatic. It is one of the best foddergrasses for swampy meadows. The fruit is collected in Prussia, Silesia, and Poland by striking the panicles over a sieve. It forms an article of commerce, and is cooked for mush. G. aquatica Sm., which is cane-like, with expanded panicles, often occurs in quantities on the edges of ponds,

Fig. 8\%.-Glyceria fluitans R. Brown. (After Nees, Gen. Germ., I. 5\%.) and in a young state forms a useful food for cattle.
264. (259) Atropis Rupr. (Puccinellia Parl.). In general like the preceding, but distinguished by the lodicules and style (see key). Fruit usually grown to the palea.

Low, salt-loving grasses, often with rigid leaves.
Species fourteen, in all the temperate zones. A. distans Griseb. is very widely distributed.
265. (260) Festuca L. Spikelets usually lanceolate, paniculate or racemed, two- to many-flowered ; flowering glumes rounded on the back below, often keeled
above, usually awned from the point, ravely below it, chartaceous to membranaceous,

Fig. 88.-Festuca orina L. D1, Fruiting bract in cross-section. IAfter Nees, Gen. Germ., I. 72.) five-nerved; style almost wanting; fruit long, usually furrowed on the inner side, often grown to the palea.

Species about eighty, scattered over all countries, especially the temperate ones.

Sub-genus I. Eufestuca. Spikelets in panicles, rarely in racemes, distinctly pedicellate; anthers and stigmas projecting from the glumes at the time of flowering. Peremnial species, separable into several sections. To this sub-genus belongs $F$. ovina L., "Sheep's Fescue," with involute, usually filiform leaves, the ligules of which are auriculate. It is distributed in numerous varieties over all the temperate countries of the northern hemisphere, preferring sandy soils and dry mountain slopes; a valuable pasture-grass, especially for sheep, in places where nothing better will thrive. $F$. rulra L., usually with runuers, and ligule not auriculate, is also a good pasture-grass. F. elatior L. ( $F$. pratensis Huds., Schedonorus elutior Beauv.), "Meadow Fescue," has flat leares with two small, falcate auricles at the base. This is a very valuable meadow- and pasture-grass, especially for the moister places, and also for lawns. Leucopoa Griseb. is a species of the section Varice. Whether $F$. quadridentuta Kunth with four-toothed flowering glumes belongs here is doubtful. This tall (3-4 in.) species of the Ecuador Audes is deadly to all cattle, but serves for covering roofs.

Sub-genus II. Vulpia Gmelin (as a genus). Spikelets in panicles or racemes ; pedicels often thickened abore ; stamens and stigmas usually remaining between the glumes during the time of flowering. Mostly aumuals. Ciemopsis De Not. (Fest. pectinella Del.), with much crowded one-sided racemes, from North Africa, belongs here. It is sometimes cultivated as an ornamental grass.

Sub-genus III. Nurdurus Reichenb. (as a genus), (Micropyrum and Festuceria Link, Custellia Tin.). Spike-
lets in simple or brauched racemes with very short pedicels appressed to the rachis; stamens and stigmas protruding. F. Lachenalii Spenn. in Western Europe.
266. (260 §) Catapodium Link. Spikelets very short pedicelled, in simple racemes.

Species two, C. loliaceum Link and C. Lolium (Bal.) Hack., in the regions of the Mediterranean.
267. ( 260 §) Scleropoa Griseb. Panicles one-sided, slightly branched. Spikelets with thick pedicels.

Species two, in the Mediterranean region, one of which, S. rigida Griseb., is also in Western Europe as far as England. Like the preceding genus, it differs from Festuca only in the punctiform hilum, and perhaps should be considered as a sub-genus.

## Sub-tribe H.-Brachypodieæ.

Spikelets like those of Eufestucere, but with simple, roundish starchgrains, and with the outermost cell-layer of the nucellus, which in most grasses disappears when the fruit is ripe, developed into a strong, thick-walled layer.
268. (263) Bromus L. (Fig. 89). Spikelets in panicles, rarely in racemes, usually large ; flowering glumes 5-9nerved, herbaceous, usually two-toothed, awned from the back below the point or from between the teeth, rarely awnless; awn sometimes straight, sometimes divergent, but never geniculate; ovary with a $2-3-$ lobed, hairy, cushion-like appendage at the summit, between the furrows of which arise the stigmas. Stigmas sessile on the anterior side; fruit linear or oblong, furrowed, adherent to the palea.

Species over forty, most abundant in the north temperate zone, some also in temperate South America, a few on the mountains of the tropics.

Sub-genus I. Festucoides. Mostly tall perennials; panicles loose; first empty glume one-, the second usually 3 -nerved ; flowering glumes short-awned ; palea with a very short fringe on the keels. Br. erectus Huds., with upright spikelets, ciliate leaves and awns half the length of the flowering glume, grows in dry meadows in Europe. On dry chalky soils it yields considerable hay and is a
valuable forage-grass for such places. The related $B$. inermis Leyss., with awnless spikelets and creeping rhizomes, is an important pasture-grass for dry climates. The rhizome of $B r$. catharti-

Fig. 89.-Promus mollis L. (After Nees, Gen, Germ., I. 75.) cus Vahl. of Chili is valned there as a purgative.

Sub-genus II. Stenobromus. Low annuals with narrow spikelets becoming broader above. Empty glumes as in Sub-genus I. Flowering glumes keeled, long-a wned; palea with a stiff fringe. Weeds. B. Tectorum and $B$. steritis L. in all Europe, and introduced in America. Anisantha C. Koch also belongs here.

Sub-genus III. Zeobromus (Serrafalcus Parl.). Annuals, with ovate or lanceolate spikelets, narrower above; first empty glume 3-5nerved, second 5-7-nerved; flowering glumes 7-9-nerved, not keeled; awn often spreading, rarely wanting; palea with a stiff fringe of hairs. B. secalinus L. ("Chess"), panicles drooping after flowering, leaves smooth; a weed among crops, in wet years, sometimes very abundant in rye. If the fruit is not separated by a chess-sieve the rye is worthless, for the flour prepared from it will be dark-colored, remain moist, aud is narcotic. Br. arvensis L., with similar panicles but hairy leaves, is less dangerous. B. mollis, with the branches of the panicle upright and hairy spikelets, growing in sandy places, furnishes a transient green forlder on light soils. Trimiusa Steud. is a species usmally having three awns.

Sub-genus IV. Libertio Lejeune (as a genus, Michelariu Dum.). Like Zeobromus, but the flowering glume
is three-cleft, three-awned, and has two lateral projections. B. Arduennensis Kunth is a species of this subgenus.

Sub-genus V. Ceratochloa Beauv. (as a genus). Spikelets lanceolate, compressed. Both empty and flowering glumes many-nerved, keeled. Ovary with three distinct elevations at the summit. $B$. unioloides Kunth ( $B$. Schroderi Kunth, Ceratochloa pendulu Schrad.). Spikelets $6-10$-flowered, compressed, arranged in loose panicles, drooping at maturity ; awns very short; from the Western United States to Chili and the Argentine Republic. A valuable fodder-grass for warmer countries, since it furnishes considerable foliage as early as January and February. In northern countries it freezes out. Sometimes grown for ornament. B. Mango Desv. was, before the introduction of the European grains, the most important cereal of the native Chilians.
269. (199) Boissiera Hochstetter. Related to the P(tppophorere by the 5-9 dorsal awns, but is a Bromus as regards habit and anatomical characters of the fruit. A low annual with crowded panicles.

Species one ( $B$. bromoides Hochst.), on the elevated plains of the Orient.
270. (261) Megalachne Steud. (Pantathera Philippi). A Zeobromus as regards its habit of growth, but with long-awned empty glumes ; flowering glumes awned from the point, faintly five-nerved ; fruit unknown.

Species one (M. Berteroniunc Steul.), upon Juan Fernandez. (Union with the Brachyporliere doubtful.)
271. (264) Brachypodium Beauv. (Hemilromus Steud.). Spikelets many-flowered, narrow, almost cylindrical, in a simple raceme (false spikes) with very short pedicels; flowering glumes usnally awned from the point, edge eutire, 7-9-nerved; palea with stiff-fringed keels; fruit grown to the flowering glume and palea.

Species six, in Europe, temperate Asia and its tropical high mountains, in North and South Africa and their central high mountains, rarely in North America. Medium grade fodder grasses. B. pinnatum Beauv. with upright, and $B$. sylvaticum $B$. with nodding racemes,
are widespread. Trachynia Link is an annual species with few spikelets.

## Tribe XII.-Hordee.

Spikelets one- to many-Howered (if many, the uppermost flower imperfect), sessile on teeth or notches of the rachis, forming a spike.
A. Stigme one, spike unilatercl. . . . . 272. Nardus. Note.-Compare Streptogyne with 2-3 stigmas.
B. Stigmas two, spike symmetrical.
a. Spikelets solitary at the notches of the rachis. $\alpha$. Spikelets in the median line of the rachis, that is, the glumes having their backs turned to the hollow surface of the rachis.
I. Spikelets many-flowered. . 273. Lolium.
II. Spikelets two-flowered ; flowering glumes three-cleft. . . . . . . 274. Kralikia.
III. Spikelets with one lower of flower, and one upper ¢ flower; flowering glumes awnless. . . . . . . 275. Kerinozoma.
IV. Spikelets one-flowered.
$1^{\circ}$. Dioccious. Empty glumes grown to the rachis for half their length.
277. Jouvea.
$2^{\circ}$. Hermaphrodite. Empty glumes free.

* Empty glumes two, the lower shorter. Callus of flowering glume hairy. . 276. Oropetium.
** Empty glume one. Callus naked. 278. Monerma.
*** Empty glume one. Joints of the rachilla with wing-like appendages. . . . . 278a. Ischnurus.
$\beta$. Spikelets transverse, that is, the sides turned toward the hollowed surface of the rachis.
I. Spikelets 1-2-flowered in a slender, articulate spike, each joint of which separates with the adjoining spikelet at maturity. $1^{\circ}$. Empty glumes two, exceeding the flowering glumes.
> * Flowering glumes awnless; callus naked. . . . . . 279. Lepturus.
> ** Flowering glumes awned; callus hairy. . . . . . 280. Scribneria. $2^{\circ}$. Empty glume one, very small.

281. Psilurus.
II. Spikelets two- to many-flowered, usually in stout spikes whose joints either do not disarticulate at maturity, or which separate with the spikelet above (Heteranthelium excepted).
$1^{\circ}$ : All the spikelets fertile or the lowest only sterile.

* Flowering glumes with a distinct callus which is limited by a furrow at the base; falling off at maturity, each with a single grain which is grown to the palea. 282. Agropyrum.
Flowering glumes without a callus, persistent at matuxity ; grain free.
† Empty glumes subulate, onenerved. . . . . 284. Secale.
$\dagger \dagger$ Empty glumes oblong, truncate, two-keeled. . 283. Haynaldia. $\dagger \dagger$ Empty glumes ovate, three- to many-nerved. . 285. Triticum.
$2^{\circ}$. The one fertile spikelet alternating with three sterile ones which consist of numerous long-awned glumes.

286. Heteranthelium.
b. Spikelets 2-6 at each joint of the rachis.

Note.-Compare the lower joints of the axis in Scribneria.
$\alpha$. Stamens three in each flower.
I. Spikelets one-flowered or with a rudiment only of a second. . . . 287. Hordeum.
II. Spikelets two- to many-flowered.
$1^{\circ}$. Empty glumes a little smaller than the flowering glumes. . . . 288. Elymus.
> $2^{\circ}$. Empty glumes very small or none. 289. Asprella. $\beta$. Stamens 10-40 in each f flower. 290. Pariana.

## Sub-tribe A.-Nardeæ.

Spikes unilateral; stigmas one; starch-grains compound.
272. (271) Nardus L. Both series of spikelets very close together, apparently mited on the inner side of the

Fig. 90.-Nurdus stizctı L. (After Nees, (xen. Germ., I. 86.) N, Apex of continuous rachis. Spikeiets one-flowered; empty glume one, very small, grown to the rachis, often indistinct; flowering glumes arranged in the median line of the rachis, awned. Spikelets not opening in flower. (The glumes remain almost embracing each other, only at the apex of the spikelet is a small opening for the stigma and anthers.)

Species one ( $N$. stricta L.) (Fig. 90). Leaves subulate, rigid. By the distichous arrangement of the short branches of the rhizome this grass forms a very thick and dense turf. It grows in moist calcareous soils throughout Europe and Northern Asia. It is a useless grass, crowding out better sorts.

## Sub-tribe B.-Lolieæ.

Spikelets standing in the median line of the rachis; starch-grains usually compound.
273. (265) Lolium L. Rachis not articulate, terminal spikelets with two empty glumes; lateral spikelets with the upper (outer) one only, or at most a rudiment of the lower.

Species six, in Europe, North Africa and temperate Asia, often introduced into other countries. L. perenne L., English "Ray-grass" (Fig. 91), is a perennial, with leaves folded in the bud, and awnless spikelets. A valuable pasture-grass upou fresh, heavy soils, and much prized for lawns. L. Itclicum A. Braun, Italian "Raygrass," lasts $2-3$ years ; leaves rolled in the bud; spike-

Fig. 91.-Lolium perenne L. (After Nees, Gen. Germ., I. 78.)
lets mostly awned. A tall-growing species, and can therefore be well recommended for mowing. Very profitable when irrigated. L. temulentum L. "Darnel" (Cropolia Schrank. as a genus), annual, flowering glumes elliptical at maturity ; empty glumes as long as or longer than the spikelets. A weed among grain crops, troublesome in wet years. The grain, as well as that of the related $L$. remotum, which is frequent in flax fields and distinguished by the shorter empty glumes, contains a narcotic principle (Loliin) soluble in ether, which
causes eruptions, trembling, and confusion of sight in man and in flesh-eating animals, and very strongly in rabbits, but it does not affect swine, horned cattle, or ducks. Arthrochortus Lowe belongs to this genus.
274. (272) Kralikia Cosson \& Durieu. Spikes slender ; spikelets very small ; empty glumes two ; callus of the flowering glumes bearded.

Species one ( $K$. Africana C. \& D.), in Algiers.
275. Kerinozoma Steud. A much-branched prostrate grass with only $3-5$ spikelets in each spike, with a small cup-shaped, membranaceous, bracteate leaf enclosing the base. Terminal spikelet none. Upper leaf-sheath inflated, its blade short.

Species one ( $K$. littoralis Zolling.), in Java.
276. (273) Oropetium Trin. Adwarf grass, the minute spikelets almost immersed in the notches of the flexuose rachis. Flowering glumes awnless.

Species one ( $O$. Thomceum Trin.), in the East Indies.
277. (194) Jouvea Fournier. Only the of plant known. First empty glume cartilaginous, and, like the second, grown fast to the rachis for half its length.

Species one ( $J$. straminea Fourn.), on the sea-coasts of Mexico. A rush-like, thorny grass.
278. (270) Monerma Beauv. Spikes cylindrical, subulate, articulated. Spikelets deeply immersed in the rachis, awnless, terminal with two, others with one empty glume, these coriaceous ; flowering glumes membranaceous.

Species three, one (M. subulata Röm. et Schult.) in the mediterranean regions, South Africa, and Australia ; one from the Pacific Islands and Australia to Ceylon; the third in Madagascar.

278a. Ischnurus Balf. fil. Like Monerma, but the joints of the rachilla are provided in front with wing-like appendages which almost cover the deeply-immersed empty glumes. Spikelets not filling up the excarations in the rachis; the spike is therefore pitted.

Species one (I. pulchellus Balf. fil), a native of Socotra (an island east of Tropical Africa).

## Sub-tribe C.-Leptureæ.

Spikelets transverse; starch-grains compound.
279. (269) Lepturus Brown. In habit like the genus Monerma, but with two nearly equal, approximate empty glumes opposite in the terminal spikelet. Low amurals.

Sec. I. Eulepturus. Spikelets one-flowered.
Species one, from the Baltic Sea to Egypt along the coast; the second in the Mediterranean regions and through the Orient and Hindostan to Australia; the third from Persia to Afghanistan.

Sec. II. Pholiurus Trin. (as genus). Spikelets twoflowered.

Species one, L. Pannonicus Kunth, from Hungary to Trans-Caucasia.
280. Scribneria Hackel. Rachis not articulate nor excavated; spikelets frequently in pairs (one pedicellate) on the lower joints [solitary above]. Empty glumes somewhat unequal, excentrically keeled, coriaceous; flowering glumes keeled, membranaceous, two-toothed, awned between the teeth. The rachilla prolonged beyond the flower and bearded at the point. Stamens not exserted at flowering time. Stigma short. Grain linear, laterally compressed, unfurrowed.

Species one (S. Bolanderi Hack., Lepturus Bolanderi Thurb.). A low, delicate annual in California and Oregon.
281. (270) Psilurus Trin. A delicate grass with very long, slender, curved spikes, the joints not hollowed out. Empty glumes many times shorter than the flowering glumes, the latter

Fug. 91a.-Scribneria Bolanderi Hackel. A 1, Pedicellate spikelet viewed from the outside. $A 2$, Same seen from the inside. $a$, Floret with prolongation of rachilla detached. (After Hackel, Bot. Gazette, vol. xi. pl. 5.) finely awned from the point; rachilla prolonged beyond the flower, often having a second flower; stamen one.

Species one ( $P$. nurdoides Trin.), South Europe to Afghanistan.

## Sub-Tribe D.-Triticeæ.

Spikelets transverse (side against the rachis); empty glumes opposite; starch-grains simple.

2太2. (266) Agropyrum Gärtn. (Elytrigiu Desv.). Spikes with the rachis articulate or continuous; spikelets more

Fig. NQ-Agropyrum repens (L.) Beauv. (After Nees, Gen. Germ., I. 80.) or less compressed, $3-\infty$-flowered, all fertile; empty glumes not inflated, narrower than the flowering glumes, lanceolate or linear; flowering glumes coriaceous, rounded on the back or slightly keeled above, $5-7$-nerved, awnless or awned, the uppermost often sterile; grain compressed on the back, hairy at the apex, slightly sulcate.

Species thirty-two, distributed throughout all temperate countries.

Sec. I. Agropyrum. Perennials. Spikes usually long aud narrow with terminal spikelets; empty glumes not keelerl, 3-5̃-nerved. A. repens Beauv. (Triticum repens L.). "Couch grass," "Witch grass" (Fig. 92), has creeping rhizomes, flat leaves, somewhat acnte empty and flowering glumes. Common in Europe and Asia, also in North and South America. A troublesome weed in cultivated fields. The somewhat superficial, creeping rumers may be removed by harrowing and raking them off, or killed by deep ploughing; and they may be smothered by thick planting of leafy plants, like the clover. For poor pastures it is, especially when young, valuable fodder-grass aud is
useful to fasteu the sand on river banks. The juicy rhizomes and rumers are a nomrishing food for cattle; they contain 3 尔 sugar and 6-8 $\%$ Triticin, a gummy carbohydrate, and are ofticinally known as "roulix gromimis." The extract acts as a solvent upon collections of the mucous membranes and in affections of the intestinal canal. A syrup and eveu alcohol are also made from it. [A. gloncum R. \& S. (?), "Blue Stem," is a valued haygrass in Montana.] A. junceum Beauv. is distinguisher by its involute leaves, obtuse spikelets, and articulate spikes. It serves to fasten down the dunes upon sandy coasts. Roegneria C. Koch is a species of this section.

Sec. II. Eremopyrum Jaub. d: Spach. (as a genus). Spikes short, usually without terminal spikelets ; empty glumes keeled, one- or indistinctly five-nerved.

Species seven, mostly oriental ammuals. T.cristatum Schreb. extents as far west as Hungary and Vienna.
283. ( $266 \$$ ) Haynaldia Schur. Rachis of the very compact spike articulated; spikelets not inflated; twoflowered; empty glumes flat or channelled between the two keels, long-awned ; Howering glumes keeled, awned below the point; grain free, laterally compressed, narrowly sulcate.

Species two, one ( $H$. villosa Schur.) in the Mediterranean and steppe regions as far as Hungary; the other (H. hordeacea Hack.) in Algiers.
284. (267) Secale L. Spikes without terminal spikelets, somewhat loose, rachis articulate (cultivated forms excepted) ; spikelets not inflated, two-, rarely threeflowered, the lower flowers approximate ; empty glumes subnlate-pointed; flowering glumes long-awned from the point, sharply keeled to the hase; keel fringed; grain slightly compressed laterally, deeply sulcate, hairy at the apex, free, without epiblast; embryonic rootlets four.

Species two, S. frogile Bieberst., with long awns to the elupty glumes extenting far heyond the flowering glumes, in the sandy plains of Hungary and Sonthern Russia, annual ; and S. cererte L., Rye (Fig. 93), with subulate-pointed empty glumes which do mot exceed the flowering glumes. The original species (called S. mom-
tanum Guss.) grows upon mountains of Spain and Moroceo, through Silicia, Dalmatia, Servia, Greece, Asia Minor, Armenia, Kurdistan as far as Central Asia. It is peremnial and has

Fig. 93.-Secale cereale L: $A$, Spike (after MullGuyot). K1, Fruit from the front; $K:$, from the side; $K 3$, in cross-section. (After Nees, Gen. Germ. 81.) an articulate rachis, both of which characteristics are lost in culture. However, rye stubble, if it stands a long time in the field, will sprout again, a thing that never happens with wheat and barley because their original forms are annual. At present it is mainly cultivated in northern Europe (to 691 ${ }^{\circ}$ north latitude), and also in North America. It is the chief cereal of the German and Slavonic nations. Its variations are unimportant. The fruit furnishes the wellknown black flour used in making bread. In the green state rye forms a nourishing fodder. The straw is prized on account of its length; it is useful for making hats, and in the manufacture of paper. The bran is used for cattle-feed, for poultices, etc., and the grain for the distillery." Its culture in Europe is not so old as that of the other cereals. It was unknown to the people of Western Europe

* For the details on cereals see Körnicke and Werner, " Handbuch des Getreidebaus" (Bonn, 1885), upon which are based many of the statements here given,
in the earliest prehistoric times, and appeared in Eastern Europe in the brouze age, as is proven especially by the remains found at Olmuitz. The people of Eastern Europe probably received it from the natives of Sonthern Russiat and Western Asia, who probably were the first to cultivate the plants which grew wild among then.

285. (268) Triticum L. Spikes with a (rarely aborted) terminal spikelet ; rachis articulate (cultivated forms excepted) ; lowest 1-4 spikelets smaller than the others, awnless, sterile (occasionally fertile in the cultivated

forms). Fertile spikelets inflated or somewhat rentricose, $2-5$-flowered, ripening only $1-3$ fruits. Spikelets, especially the lowest, closely imbricated ; empty glumes broad, always with one to many awns, or at least with a
blunt or toothed apex ; flowering glumes rounded on the back, often navicular, many-nerved, ending in one to several teeth or awns; fruit very slightly compressed laterally, deeply sulcate, hairy at the apex, free. Emhryo with epiblist and three rootlets. Always aunual.

Two illy defined sections:
Sec. I. Egilops L. (ats a genus). Empty glumes flat or rounded on the back, not at all, or indistinctly, keeled.

Species twelre, in Southern Europe and the Orient to Afghanistan and Turkestan. AE. ovute L. with 3-5. awns on the empty glumes, $E$. trinncialis (Fig. 94), three awns, etc., in Southeru Europe; the former forms a cross with $T$. sutivum. The spikes fall off as a whole, separating below the lowest fertile spikelet; the empty glumes of several Oriental species are one-awned or awnless and the spikelets fall off singly. These form transitions to the following section.

Sec. II. Sitopyros. Empty glumes sharply keeled. To this section belong the most important grains. They can be traced back to three species.
a. Terminal spikelet aborted, often scarcely visible.

Palea falling into two parts at maturity. Lateral
teeth of empty glumes acute. . 1. Tr. monococcum.
b. Terminal spikelets developed; palea remaining entire ; lateral teeth of the empty glumes obtuse.
$\alpha$. Empty glumes shorter than any of the flowering glumes, chartaceous; palea as long as flowering glumes.
2. Tr. sativum.

乃. Empty glumes as loug as or longer than any of the flowering glumes, chartaceous, lanceolate; palea of the lowest flower half as long as its glume.
3. Tr. Polonicum.

1. Tr. monocorcnm L. (Fig. 103). Spikes compact, articulate, joints readily separating (even in cultivated forms), every spikelet with one awn; usually only the lower, very rarely also the upper, flowers maturing their fruit. The wild plants (Tr. Breboticum Boiss., C'rithorlium regitopoides Link) scarcely distinguished from the
cultivated as varieties. They grow from Achaia through Thessaly (where they corer eutire hills), Servia, Asia Minor, the Crimea, and Caucasian countries to Mesopotamia. This species is mostly cultivated in Spain, only rarely in France, Germany (especially in W iirtemberg and Thuringia), and Switzerland, and upon poor and rough places that are not suited for other rarieties of wheat. The finding of its fruit in the Lake dwellings belouging to the Stone age of Switzerland and Hungary, as well as at Hissarlik (Troy, according to Schliemann), proves its great antiquity. It is not so oftell used for bread as for mush and "cracked wheat," and as fodder for cattle. It varies but little.
2. Tr. sativum Lam. (in a wider sense), Wheat (Figs. 95-102), original form muknown. Many races and varieties produced by culture, of which those with the rachis articulate are probably most closely related to the original form. The brittleness of the rachis exists, however, in different degrees and is correlated with the more or less firm closing of the fruiting glumes. Three races:
I. Rachis articulate at maturity ; grain entirely enclosed by the glumes, not falling out when thrashed (however, it is not grown to the glumes).
$1^{\circ}$. Spikes loose, almost four-sided when seen from above; empty glumes broadly truncate in front, with a very short, obtuse middle tooth, obtusely keeled. . a. Tr. sat. Spelta.
$2^{\circ}$. Spikes very dense, laterally compressed; empty glumes tapering, with an acute middle tooth ; sharply keeled. . . . b. Tr. sat. dicoccum.
II. Rachis not articulated at maturity ; grain visible between the somewhat open fruiting glumes, easily falling out. c. Tr. sat. tenax.
a. Tri. sut. Spelta (Tr. Speltu L.), Spelt* (Fig. 101). There are awned and awnless, hairy and smoothspiked, white, gray-blue, and reddish varieties. One of the oldest grains. It was anciently the chief grain in Egypt and Greece, and was cultivated everywhere throughout the Roman Empire and distributed through its colonies. Its culture has continually decreased mutil, at present, it has disappeared from Egypt and Greece, and has hecome very rare in Italy and France ; and even in S. Germany and Switzerland, where it is still the most cultivated, it is continually becoming rarer. It is yet important in N. Spain. The winter beardless spelt, a white-spiked, awnless variety, is the most profitable. Spelt possesses undoubted adrantage over the naken wheats only when grown upon poor soil, in small fields and with moderate culture ; its demands are less, it is more certain, liable to fewer cliseases, and not at all subject to the attacks of birds. Upon better soil and with reasonable cultivation the returns are better from common wheat.
b. Tr. sut. dicoccum (Tr. dicoccum Schrank) (Fig. 102). Always awned; spikes broader on the two-ranked site, narrower on the imbricated one. Cultivated from the most ancient times (Lake dwellings of Rohenhausen), but always more sparingly than Spelt, and at present only in S. Germany, Switzerland, Spain, Servia, and Italy. It is a summer grain, and is used mainly as mush and for making starch. The best kind is the so-called Rice-spelt (Reisdinkel).
c. Tr. sut. tenax. This falls into four poorly characterized sub-races which in many characters overlap, and each of which, in turn, possesses numerons varieties, according to the awns, hairiness, and color of the spikes.

[^5]$1^{\circ}$. Empty glumes distinctly keeled only in the upper half, rounded or only slightly keeled in the lower half.

* Spikes long, more or less loose, somewhat dorsally compressed.
$\alpha$. Tr. sat. vulgare.
** Spike short, dense, distinctly foursided. . . . $\beta$. Tr. sat. compactum.
$2^{\circ}$. Empty glumes sharply keeled at the base.
* Fruit short, thick, not compressed, broadly truncate above.
r. Tr. sat. turgidum.
** Fruit oblong, narrower, somewhat laterally compressed, and somewhat acuminate. . . . . $\delta$. Tr. sat. durum.
$\alpha$. Tr. sat. vulgare (Tr. vulgare Vill.), common wheat (Figs. 96, 97). The principal sub-varieties are awnless and bearded (awned) wheats, with naked or hairy, whitish, bluish, blackish, or reddish spikes. It has been known from most ancient times (grains found in Egyptian Pyramids) ; is generally cultivated as far north as its cultivation is possible (Norway, $69^{\circ}$ N. Lat., Alps at 1400

metres altitude), and its culture is very import-
ant in N. America; in Chili only in S. America. The most valuable German, American, and Hungarian kinds belong to this rariety. It is cultivated either as a summer or winter grain.
乃. Tr. sat. compactum (Tr. compactum Host.), "Dwarf Wheat," "Herlgehog Wheat." Spikes 3-4 times longer than broad, awned or awnless; culms and spikes very rigidly upright. A very old cultivated form (Lake dwellings of Robenhausen!) at present mainly cultivated in the Austrian Alps, Würtemberg, Alsace, Switzerland, Chili, and Turkestan. The awned kinds are called "Hedgehog Wheat." The Abyssinian "Dwarf Wheat" forms a special group. On account of their stiff culms the dwarf wheats are less liable to lodge. Certain kinds, like the yellow winter Hedgehogwheat, are peculiarly adapted to rough and stormy regions. The yellow summer Hedgehog wheat is also profitable on poor soils.
$\gamma$. Tr. sat. turgidum
(Tr.turgidum L.) Fig. 98.-English (Fig.98), English wheat. Culms

tall, thickish, stiff and upright, with large,
thick, and dense four-sided spikes; leaves broader than in $T$. vulgure, and usually clothed with velvety hairs. It is especially cultivated in the Mediterranean countries, more rarely in England and Germany. The English wheat yields very good harvests, but its flour is poor in gluten and usually grayish ; it is therefore less adapted to cooking, and prized less. In Germany most kinds are not sufficiently hardy to winter well.

The Miracle wheats ("Egyptian" wheats) (Tr. compositum L.) are formed by a special group of varieties, with branched spikes. Originally a sport,they have become strongly hereditary. Their culture is not profitable, for the grains are very unequally developed.
ס. Tr. sat. durum (Tr. durum Desf.), Hard or Flint wheat (Fig. 99). Recognizable by its long, bristling awns. Culm often filled with pith or solid ; fruit very hard, usually vitreous,

Fig. 100.-Polish Fig. 101.--Bearded Wheat. Tr. Po- Spelt. Tr. sutilonicum. vum Spelta. rarely mealy. Cultivated in the Mediterranean countries, the most important grain in Spain, and also predominating in N. Africa. Of scarcely any importance in Germany. Several varieties have coal-black awns.
3. Tr. Polonicum L., Polish wheat (Fig. 100). A very striking species with large, compressed,
mostly hlue-green spikes. Spikelets appearing as if cut off transversely becanse the third and fourth flowers scancely reach to the point of the two lower ones; flowering glumes compressed, navicular, many-nerved, awned; fruit 8-12 mm. long. Original form unknown ; perhaps not a true species ; it may have originated by culture. It gives rise, but rarely, to a fertile cross with Tr. sativum; while the crossing of the sutivum races among each other is perfectly fertile, that of the monococcum with the sativum races is entirely infertile. Poland is by no means its native country ; more likely it originatedinSpain, where it is now cultivated on a large scale in Leon, Old Castile, and the Balearic Isles. It is also still cultivated in Italy and Abyssinia, but in other places its culture, if
 it ever existed, has Fig. 102.-" Ger- Fig. 103.-One.graindisappeared. The man" Wheat. ed Wheat. $T$. long and slender coccum. fruit resembles rye, but is on the whole larger, and under the name of "Giant Rye" it has sometimes been fraudulently sold to farmers. The returns are poor on account of its having few kernels.

Wheat flour furnishes the best and whitest bread, yet not all wheat is alike adapted for bread-making, since for this purpose a sufficient
amount of gluten, such as is found in the half hard and half soft kinds, is indispensable. Pronounced soft wheats, like the English, esperially those grown in a moist climate, need the addition of flour of the hard-fruited races before baking. By themselves alone they are better adapted for starch-making. The especially hard wheats are over-rich in gluten, and the food baked from them is therefore too firm. They are accordingly used for macaroni and for making cracked wheat and mush. The straw is shorter than that of rye ; an especially short aud delicate-stalked kind is produced in Tuscany by thick sowing on poor soil, and used for making Florentine hats.
286. Heteranthelium Hochst. An amual grass, with spikes having many bristles. Empty glumes bristlelike, with hairs arranged like the barbs of a feather. Flowering glumes warty and with awl-shaped awns. Abore the two fertile flowers is a pedicel with a tuft of sterile, subulate or awn-like glumes.

Species one (H. piliferum Hochst.), in the Orient.

## Sub-tribe E.-Elymeæ.

Spikelets 2-6 on each notch of the rachis, forming a brauching system in which one spikelet (the middle one) represents the primary, and the lateral spikelets the secoudary and tertiary branches. Rarely the primary branch is aborted aud the secondary ones only are present. The terminal spikelet when present has both empty glumes together with the flowering glumes in its median lines. In the lateral spikelets, on the contrary, they are thrown out of this line and occupy the place that is left to them from the crowding together of the spikelets; that is, they usually stand close together in twos in front of each spikelet, aud therefore often apparently decussate with the median line of the spike. Stamens three.
287. (274) Hordeum L. Empty glumes narrow, usually subulate, all together forming a kind of involucre around the spikelet; flowering glumes in the median line of the rachis (as in Lolium) five-nerved, extending into a strong awu; graiu usually adherent to the glume, hairy at the apex, usually sulcate, without epiblast.

Species about sixteen, in Europe, temperate Asia, North Africa, and North and South America.

Sub-greuns I. Zeocriton Beaus. (as a genus) (Critesion Rafin.). Rachis (cultivated forms excepted) articulate, each joint falling off with the group of spikelets attached above it. The middle spikelet fertile, the lateral ones

Fig. 104. - Two ranked barley. Hordeum sutivum distichon.

Fig. 105.-Hordeum sativum hexastichon. B3, Group of three spikelets. $B$, a spikelet from behind; $B 1$, from in front. $K 1$, Fruit from in front; $K 2$, from behind. (After Nees, Gen. Germ., I. 83.)

Fig. 106.-Common 4rowed barley. Hordeum sativum vulgare.
mostly short-perlicellate, rarely sessile, sterile (fertile only in cultivated forms) ; terminal spikelet aborted; fruiting glumes persistent on the perlicels.

Species twelve, among which are $H$. murinum L., with pedicellate lateral spikelets, a widespread weed; 11 . sutivum Jessen, Cultivated Barley, with sessile lateral
spikelets, and empty glumes obtuse. This undoubtedly originated from M. spontoneum C. Koch, which grows wild from Asia Minor and Cancasian cometries to Persia and Beloochistan, as well as in Syria, Palestine, and Arabia Petrea. The two-rowed, cultivated barley is distinguished from it only by the character due to cultivationviz., the non-articulate axis and somewhat shorter awns. Sub-species (Races):
a. All spikelets fertile, therefore six rows of fruit. $\alpha$. The six rows distinctly separated.

> b. H. sat. hexastichon.
$\beta$. Only the middle rows distinctly separated, the side rows overlapping.

> c. H. sat. vulgare.
b. Ouly the middle spikelet of each cluster of three fertile. . . . . . a. H. sat. distichon.
a. H. sut. distichon (H. distichon L.), two-rowed Barley (Fig. 104). Spikes strongly compressed laterally, the sterile lateral spikelets appressed to the rachis, with or without stamens. Falls into numerous varieties, the most important of which are:
$\alpha$. mutuns. Lateral spikelets distinct, spikes usually uniform in width, awns appressed to the spike ; spike loose, narrow, usually wodding.
$\beta$. erectum. Like $\alpha$, but with broad, upright spikes. $\gamma$. Zeocriton, "Peacock Barley," "Rice Barley." Like $\beta$, but the spikes tapering toward the end, and the awns diverging.
ס. mocrolepis, with aborted lateral spikelets and broad, empty glumes in the middle spikelet.
$\epsilon$. reficiens. Like $\delta$, but the empty glumes narrow.
Besides these there is one variety with naked fruit ( $H$. nudum L.), and several sub-varieties distinguished only by the pale yellow or black color of the spikes.

The two-rowed barley is cultivated especially in Central Europe (in Switzerland as far as 2000 metres above the sea) and England, and the varieties $\delta$ and $\epsilon$ in Abyssinia.
b. II. sat. hexastichon (H. hexastichon L.), six-rowed
harley (Fig. 10:). Spikes romudish in circumference ; all six rows diverging uniformly and forming a six-rayed star when viewed from above; joints of rachis very short, therefore the spikelets are closely imbricated. Very widespreal, even in prehistoric times (Lake dwellings), but at present it is cultirated only in Southern Europe, rarely in Switzerland and in Germany.
c. H. sut. vulgare ( $H$. vulgore L.), irregularly ranked or four-rowed harley (Fig. 106). Spikes dorsally compressed ; the middle row more appressed to the rachis than the irregular rows of the lateral spikelets; spikes loose, often moddling. This race seems to be of later origin. Its variety pullichum (with pale yellow spikes) is the barley most frequently cultivated in Northern Europe (Noway to $78^{\circ}$ ) and Northern Asia. It is usually raised as a summer grain, and its period of vegetation may be limited to ninety days. In Central Europe, where its culture was earlier introduced, it is becoming gradually supplanted loy the two-rowed, and especially by the Chevalier barley. The greater amount of gluten which it contains makes it less adapted for beer-brewing; besides, on good soil the produce of the two-rowed is greater than that of the fomrrowed, while the latter surpasses it on poor land. The varicty cromlescens, with the gray spikes, is more frequently cultivater in Southern Europe and Northern Africa. A special series of varieties is formed by the naked-fruited barleys (H. copleste L.) as well as the Himalaya barleys, among which is the remarkable hereditary malformation ( $H$. trifurcatum) with three-horned flowering glumes. Between the four-rowed, six-rowed, and two-rowed barleys are transition stages (e.g., var. intermedium Kiorn, aud H. Konfinanni Regel), in which all the spikelets are fertile but the lateral ones are awnless. These are spontaneons variations and mot crosses, for the majority of barleys, especially the six-rowed, bear cleistogamic flowers, so that a cross in the open air is impossible.

How barley was used in ancient and in prehistoric times is uncertain. At present it forms the most important cereal of the far North. In Central Europe it is userl only for brewing beer and for soup, and in South Europe mainly as food for horses. It is used for bread also in Asia, especially in Thibet, and in North China amd Japan. North America produces considerable quantities of it; South America, on the contrary, very little. A mucilaginous tea, used as a medicine, is made from the naked barley (officinally known as "Hordenm deconticutum"). Malt and the extract of malt are also medicines.

Sub-genus II. C'rithops.s.s Jaubert (as a geuns. Rachis articulated ; spikelets in twos, sessile, fertile ; fruit persistent; apical spikelet with four decussating empty glumes, two of which are in the median line of the flowering glume.

Species one (E. Delileanus Schult.), in the Orient.

Sub-genus III. Cuviera Köl. (as a genus). Rachis continuous; spikelets in twos or threes, all fertile; fruiting glumes falling off from a distinct pedicel ; apical spikelet with two opposite empty glumes in the median line of the flowering glume.

Species three (H. sylvaticum, H. crinitum, H. Caput-Medus(e), in Europe and the Orient.
288. (275) Elymus L. (Fig. 107). Rachis usually continuous; terminal spikelet with two empty glumes lying in the median line of the flowering glume, one of them frequently aborted; lateral spikelets in groups of from two to six, all fertile; fruiting glumes falling off with a joint of the rachilla; empty glumes nar-row-linear, short-awned or awn-like; flowering glumes somewhat shorter, oblong or lanceolate, not keeled, five- Fig. 10\%.-Elymus nerved, awnless or awned; fruit ad- Tirginims. in After herent.

Species about thirty, throughout all temperate coum-
tries excepting Australia and South Africa. Tall, rigid, peremnial grasses.

Sec. I. Sitomion Rafin. (as a gemus) (Polyontherix Nees). Rachis articulate; empty glmmes usually twoto many-cleft, long-awned.

Sec. II. Clinelymus. Lathis coutinnous; empty and flowering glumes awned.

Sec. III. Psammelymus. Like Sec. II, but the empty and flowering glumes awnless. To this section belongs $E$. crenurius L., which has long, creeping rhizomes, stiff leaves, elongated ligules, and more downy flowering glumes. On the banks of the North and Baltic Seas, rarely inland, thence extending through Russia aud North Asia to North America. Very well adapted to binding drifting sands, and often planted for this purpose. In Iceland bread is made from the fruit.
289. (276) Asprella W. (Hystrix Münch, Gymnostichum Schreb.). Like the precedting, but the spikelets are usmally in pairs on short perlicels; empty glumes wanting or appearing as simple rudiments in the lowest spikelets of each spike.

Species four, two in N. America [(A. Mystrix Willd. and A. C'nlifornica Benth.) ], one in Siberia, and one in New Zealand.

## Sub-tribe F.-Parianeæ.

Spikelets usually in sixes at each joint of the rachis, forming a false whorl which consists of two opposite groups of three; in one the middle spikelet (primary branch) is of and in the other of all the lateral spikelets are of on broad pedicels which are grown together; empty shmes (apparently) decussate with the flowering ones. The of spikelet stands farther in. The terminal spikelet is solitary, large, of, with opposite empty glumes in the median line of the tlowering glumes. All the spikeletsare awnless. Stamens $10-40$ in each ô Hower. Fruit as in Tritica.
290. (81) Pariana Aubl. Grasses with hroad, somewhat petiolate leaves. The \& spikelets form an involucre around the of and fall away with it.

Species ten, in tropical South America. Eremitis Diill. appears to be a species of this genus whose flowers are ahorted, having only one stamen in each \& flower.

## Tribe NII.-Bambusea.*

Spikelets 2-8-, rarely only one-flowered, in panicles or racemes, mostly arranged in tufts or false whorls at the nodes of the branches of the panicle. Empty glumes two to several, increasing in size upwards, shorter than the succeeding flowering glumes; buds developing into spikelets sometimes appear in axils of the lowest empty glumes ; flowering glumes many-nerverl, a wuless, or rarely with short, straight, terminal awns ; palea two- to manynerved, ravely nerveless; scales or lodicules usually three, remarkably large, rarely fewer or wanting; stamens 3-6 to many; styles 2-3, often grown together at the base; fruit free; leaves usually articulated with the sheath.
[Large, often tree-like, peremial grasses with woodly, rarely herbaceons, culms. The largest species are 30 cm. in diameter aud 40 m . high. The rhizome lasts many year's, and in most species consists of nmmerous short, entwined branches which send up ummerous densely-crowded culms forming clumps. Bamboo forests of these species consist of such giant bushes intermingled with trees. Other species (Brambusa villosula Kurz., Melocanna brmbusoiles Trin., etc.) do not form clumps, but the culms, standing $30-60 \mathrm{~cm}$. apart, often cover extended areas with a thick forest-like growth. In yet other species, for example those of Phyllostrachys, the rhizome, which bears larger or smaller chmps, sends out long creeping branches that here and there produce solitary culms; these are upright, the outer ones in each chump bending or hauging over. Some species are climbers. Branches numerous, usually forming a crowded half-whorl at the norles; sometimes all the nodes bear branches, sometimes the lower part of the culm is naked, in the upper portions the branches are often single, and in many species two-ranked; the culms and

[^6]hranches of some species are thomy on accome of numerous hard and pointed twigs (aborted branches) ; a circle of secondary roots, which oceasionally become thom-like when they do not reach the gromud, frequently occur on the lower calm-nodes below the insertion of the branches; the leaf-bliule is often short, usually with a short petiole and jointed at the base, frequently deciduous; sheaths often fringed at the thonat; the long nerves of the blade are bound together in many species by prominent cross-nerves.

After the ripening of the seed, the ground hecomes covered with comntless young plants with slender, pliant stems, and a thick foliage, resembling a meadow of wasing grasses. This growth lasts many years, until the rhizomes have attained their full size, when the culns, some of which have been formed each preceding year, for the first time attain their full height and thickness. In the tropics a number of young culms in each clomp shoot up during the rainy season, often attaining their full height (even to 40 m .) in from 40 -60) dars. The entire internodes of the growing culms, and the lower part only of those which are full grown, are smromuled by large, parchment-like sheaths which are freguently corered with long deciduons hairs, and which below bear small dry membranaceous hades that hecome larger and leaf-like above. In this condition the culms have no branches and are soft, but they beeme lignified towards the end of the first year, and hranches and leaves are developed at the same time. In regard to flowering, we may distinguish between those that bloom frequently and those which rarely flower.

Many species (Arundinarion Wightiona Nees, upon the Neilgherries, species of Guadure and Chusquert bloom anmally, and the panicle is terminal on the leafy branches. In others (Dendrocalamis strictus Nees', single culms shed their leaves and become corered with panicles of flowers, while others again retain their foliage. Upon these species, which are of frequent occurrence in all the East Indies, blooming culms may consequently be found nearly every year. In other species, on the contrary,
not only all the culns of a clump become covered with flowers after they have shed their leaves, hut also all the clumps of the sane lind growing in the same comentry or province. Whole bamboo forests, so far as they consist of a single species, may be seen in bloom orer an exteuded area. This is frequently observerl in Asia as well as in America. In the East Indies the seeds, which are rich in flour, are then collected and cooked like rice, ancl are used for food by the poorer castes. But often, in Brazil as well as the Indies, misfortume follows the sudden production of such vast quantities of mealy seeds. It is the cause of an extraominary increase of mice ant rats, which, after having eaten up all the bamboo firnits, turn to the neighboring fiells, devouring the (rops of whole provinces. The German colonies in Pio Grante do sul and Sta. Catarina are visited by these pests at intervals of about thirteen years.

On the west coast of the Last Indian Peminsula the simultanenus hlooming of Brombusu armelimucers Retz. has heen ohserved at intervals of thirtr-two years (180t, $1836,1868)$. These and other facts seem to iudicate that this and other similarly related species must reach a great age before they arrive at the stage of flowering. simall plants grown from rumers and cuttings bloom in these cases at the same time as the larger growths from which the cuttings are taken. Simultanenns flowering has been observed in many species cultivated in France and Algiers. Nevertheless there are exceptions to this rule also. In many regions of the East Indies Bombusa armondinacen has bloomerl several times in other than the above-named years, and in all cases in which the simultaneons flowering of one species has been ohserved over a large area, there were straggling blooming plants in the year following. The age of the bushes appears to be only one of the conditions of flowering; weather and other circumstances also exert their influences. In special years Dendroculamus strictus blooms more profusely than at other times, mud then it not infrequently happens that all or nearly all the culms of all the clumps in one region bloom simultaneonsly. The flowering, leafless
culms always die down after the ripening of the seed. When all the culms hear flowers, the rhizomes, whose reserve material is now exhausted, produce only weak and slender stems for a long time, and only gradually regain the power of producing culms of normal height and thickness. The rhizomes become weakened in a like mamuer if all or many of the culms of a bamboo clump are cut off. In this case, also, only slender culms are produced for a series of years until their streugth is restored by the continued activity of the leaves. In greenhouses, species which would otherwise form high bushes may be checked in their development and kept small by cutting out many or all of the shorter shoots. In many cases not only the aërial portions die after flowering and ripening of seet, but the rhizomes also, and a renewal of the bamboo forests depends eutirely upon seedlings. The preceding will explain why in many species the flower's and froit have not yet beeu collected and described. In the forests it is not difficult to recognize the different species by the manner of growth, branching, sheaths and leaf-blates of the younger culns, and other characteristics ; but without flowers it is only rarely possible to determine the genus. In many species, therefore, a reliahle division into geuera has not yet been possible.]

Geogrouplical Distribution.-The Bambusere are distributed throughont the tropical zome, lut very merenly; a few species hare penetrated into sub-tropical and even into the temperate zones. The Monsoon region in Asia is rich in species (over one hundred and fifty), but in Africa there are very few (five only known up to this time); sereral occur in Matagascar. America possesses about serenty species, the Pacific Islands a few, aml North Australia two; eleven species grow in Japan, and hat one on the Kiurile Islands. In the Himalayas they extend to an altitude of 3400 m . above sea level, and still higher in the Antes. Here the species of Chusquen form impenetrable thickets, the "Carizales," covering wide areas within the tree limits; in Ecuator C'husquen "ristuta Munro reaches the snow-line. Many species
seem to have a very narrow range, and there are only two genera common to both hemispheres.

Uses.-The mere enumeration of the uses of the Bamhusere would fill many pages. They are especially indispensable to the inhabitants of India and Eastern Asia. Their uses are more limited in South America. In building houses the thicker trunks are used as posts and beams, and the weaker ones, when split, for filling up the walls and for laying the floors. [For this purpose they are split longitudinally and then pressed out flat. In this condition they consist of narrow mited strips, forming planks which may be 90 cm . broad.] The internodes cut in two longitudinally are used for tiles. Bamboo houses are durable, graceful, and, because they are airy, are especially healthful. In China all the theatres are built of bamboo. Huts for temporary residents are rery rapidly constructed from them. Both hanging and floating bridges of bamboo are in common use, especially in the Malayan Archipelagn. Water conductors are constructed either by cutting the stem in halves longitudinally, or hy hreaking through the cross-walls at the nodes. Floats made from bamboos are, on account of their containing air, capable of carrying an extraordinary load, and, for the same reason, the outrigging in the boats of the Zeylanese are made of bamboos. Slender culms serve for poles to support the betel-nut, beans and other climbing cultivated plants (they are even imported into Europe for the same purpose), and the stronger ones for palisades. From many species, especially the thorny ones, impenetrable, living hedges, and even works of defence, are constructed. Almost all the furniture of the Malars, Burmese, etc., is made from bamboos, and even in Europe bamboo is heginning to be imported for the manufacture of furniture. A single internode of a large species, in which both separating walls have been left and only one bored through, serves for a water-pail in which the water remains very pure. A dozen or more of these waterbuckets stand in every Malayan house. While still full of sap these internodes are even used as cooking
utensils. Smaller interuodes furnish pitchers, flasks, and cups ; and wide internodes, bee-hives. They are in general use for carrying-poles, and for the masts of small and medimm-sized ships. Some species supply walking-cames, especially the culms of the Japanese Phyllostuchys aud Armulinuriu. The sleuder twigs furuish pipe-stems, purses, kuife-handles, etc. Musical instrmments (flutes) are easily marle from the joints. The "Anklong" of the Malays consists of internodes of differeut thicknesses arranged accorting to their tones, and smispended near each other, and which are made to sound by striking. The living culns are made by the Malays into Eolian harps hy piercing them at certain distances and thas allowing the air to pass throngh them. The finely split bamboos open a new category of uses. [The outer green rimd of the young culms is split into narrow strips or riblons, and made into baskets and fine loraided work; for example, Chinese fans, large and small boxes, and even lats and jackets.] If the threads are boiled in lye and then rolled and scraped, ther hecome soft enough for weaving and for ropes. Coarse mats and baskets are woven from split bamboos. Bamboo mats laid orer each other like roofing-slate are a farorite roofing material in the Malayan Peninsula. The Shans and other inhalitants of the Malayan Peminsula prepare from the large parchment-like leaf-sheaths of the young culms broad-rimmed hats which are an excellent protection against the sun and rain. Bamhoos are especially important for the manufacture of Chinese paper, of which it forms the chief iugredient. The well-known Chinese umbrella consists of bamboo paper with a bamboo handle and split bamboo for a skeleton. The leaves are used for packing, filling heds, etc. The yomus shoots of the larger species are a farorite regetable with the Malays and Chinese, and are even preserved for exportation. Those of the smaller species are eaten in China like asparagus or lettuce. The importance which may be reached by the fruit of the bambons has alreaty been explained. The crops protuced are enormons and form an important article of
commerce. Abundant and good drinking-water collects in the hollows of the internodes of many large species. In those of others ( Bambusa arandinacer and Melocemmu $^{\text {and }}$ bombusoides) are formed those remarkalle silicic-acid concretions, the "Tabasheer," that are still playing an important part in the superstitions system of medicine among the Orientals. Tabasheer is considered, not merely in India but in the whole Orient and in C'lina, as a medicine of the highest value for bilious fever, dysentery, jaundice, leprosy, and lung diseases, as well as an aphondisiac. As early as the times of the Roman Empire physicians ascribed medicinal properties to it, and it attained its world-wide fame through the Arahian physicians of the tenth and eleventh centuries. It occurs in commerce in two forms, the crude and the calciner. The first, in a fresh minjured condition, is in the form of a more or less perfect cylinder with a romuled convex base, 1-3 cm. in diameter aud $1-4.5 \mathrm{~cm}$. long (Fig. 108, $B, C$, found in the hollows of the internodes upon one or both sides of the cross-wall, and as there are longitudinal furrows in the outer surface corresponding to the course of the fibro-vascular bundles, it represents an exact cast of the carity of the internode. It is translucent, gray, yellowish, bluish, brownish, or blackish in color and greasy in appearance, and covered with a chalky coating. In warm, dry air it becomes opaque and finally falls into little pieces or fine grains like sand. When fresh it contains $58-62 \%$ of water and scarcely $1_{\%}$ of organic substance; the remainder is pure silicic acid, soluble in potassimm hydrate. Calciued Tabasheer is formed by heating the crude substance red-hot, in consequence of which it is transformed into irregular, milk-white, opaque or bluish opalescent, concavo-convex pieces having an earthy taste. The origin of Tabasheer is not yet thoroughly explained; the most probable inference is that at the time of most rapid growth great quantities of water are conducted into the bamboo stems from the roots and collect in the hollow internotes. The silicic acid alkalies that are dissolved in it probably become decomposed by carbonic or organic
acids, the alkalies thus formed are re-absorbed together with the water, and a silicious jelly remains which hardens into Tabasheer. It is believed that the accounts of the ancients (Dioscorides, Plinius) which speak of $\sigma$ кк₹ $\alpha$ ofor and Saccharum do not refer to sugar, but to Tabasheẻr : perhaps the accounts of the two are confounded. The name comes from the Sanskrit (not Persian) word Tauckishica, meaning milk of the bark. [The present name in Bengal, Hindostan and in the Dekkan is Banslochan, Bans-kapúr.*]

Many species of bamboo are highly ornamental plants: the Chinese and Japanese have planted them for ages ; and in Europe, especially in the South, where many can le kept in the open air, as well as in the greenhouses of the North, their use is becoming more general and frequent.
A. Stamens three ; palea tuo-keeled ; fruit a true curyopsis (Arundinariere).
a. Spikelets two- to many-flowered (very rarely one-flowered-Phyllostachys).
$\alpha$. Spikelets with no subtending leaf.
I. Empty glumes 1-2. . . 291. Arundinaria. II. Empty glumes 3-4. 292. Arthrostylidium.
$\beta$. The 1-2 spikelets surrounded by a large leaf at their base.
293. Phyllostachys.
b. Spikelets one-flowered.
$\alpha$. In a compact globose head. 294. Athroostachys.
ß. In a one-sided spike. . . 295. Merostachys.
$\gamma$. In panicles.
I. Stem woody, leaves jointed at the base.
296. Chusquea.
II. Stem herbaceous, leaves not jointed.
297. Planotia.
B. Stamens six, fruit a true caryopsis with a delicute pericarp (Eubambusece).
a. Filaments free.
$\alpha$. Spikelets one-flowered, with many empty glumes. . . . . . . . . . 298. Nastus.

* For a more complete account of Tabasheer, see Cohn's "Beitr. z. Biologie d. Pfl.," vol. 4, part 3, and " Zeitschr. d. allg. öst. Apo-theker-Ver.," 1887, No. 9, 10 (by Poleck).
$\beta$. Spikelets two- to many-flowered.
I. Palea of the uppermost flower two-keeled; style not thickened at the base at maturity, usually falling off. . . . 299. Bambusa.
II. Palea of the uppermost flower and flowering glume one-keeled; style much thickened at the base at maturity; fitting over the caryopsis like a cap. 300. Atractocarpa.
b. Filaments grown together, forming a tube.
$\alpha$. Spikelets many-flowered, palere all two-keeled. 301. Gigantochloa.
$\beta$. Spikelets one- to many-flowered, but only the uppermost flower fertile, and this with a onekeeled palea.
I. Spikelets elongated conical, round in crosssection. . . . . . 302. Oxytenanthera. II. Spikelets ovate-lanceolate, compressed.

303. Puelia.
C. Stamens six (very rarely more); fruit a nut (with a thick, free paricarp) or berry.
a. Paler two-keeled (Dendrocalamere).
$\alpha$. Spikelets two- to many-flowered.
I. Ovary hairy at the apex; fruit a small nut.
304. Dendrocalamus.
II. Ovary naked; fruit large, fleshy (?).
305. Melocalamus.

乃. Spikelets one-flowered with a prolongation of the rachilla which often bears an upper empty glume ; fruit a nut.
I. Spikelets in distant clusters or spikes on the branches of the panicle.
$1^{\circ}$. Styles three; separate to the base.
308. Greslania.
$2^{\circ}$. Style one, very long, enclosed in a tubular beak of the ovary, with 2-3 stigmas.

* Nut almost globose, depressed, abruptly beaked. 306. Pseudostachyum. ** Nut gradually tapering into the beak. . . . 307. Teinostachyum. II. Spikelets in one to several globose heads. 309. Cephalostachyum.

1. Palea not keelerl, resembling the flowering glmmes (therefore considered wanting by many) (Melocinne(e).
$\alpha$. Lodicules 0 ; spikelets very small.
2. Dinochloa.
$\beta$. Lodicules 2-3.
I. Fruit a small nut; uppermost flower with a prolongation of the rachilla.
3. Schizostachyum.
II. Fruit a large berry; uppermost flower without a prolongation of the rachilla.
4. Melocanna.
$\gamma$. Lodicules very numerous (eight or more); anther's mostly more than six. . 313. Ochlandra.

## Sub-tribe A.-Arundinarieæ.

Stamens three.
291. (277) Arundinaria Michn. ( Miegiu Pers., Lucdolfir Willd., Triglossum Fisch.). Spikelets loose, many-flowered, elongated, panicled or racemed; empty glumes small, unequal, the first occasionally wanting; flowering glumes not keeled, sometimes short-awned; strles 2-3, free ; fruit rather long, furrowed. Suffiruticose or tall shrubs.

Species about tweuty-four, in America and Asia (as firr east as Japan and on the Himalayas); several species in Europe as ornamental platnts: A. Juponica Siel. ( Bombusu Metuke and B. mitis of the garden), which has strong, transverse nerves in the leaves, withstands, unprotected, the winters of France and South England ; A. fulcutu Nees, without transverse nerves, is from the Himalayas ; A. mecrosperme Michx. and A. tecte Muhl. occur in N. America as far north as Maryland and Illinois. The section Thumnocrl(cmus Munro (as a genus) is distinguished by its large, decituons, spathiform leares enreloping the spikelets and hanches of the panicle. $A$. (Thermmocrtumns) spothifforc lingrall, a widespread species in N.W. Himalayas between 2500 to 3400 m , abore sea level, furnishes pipe-stems which in Northern India form an important article of commerce.
292. (278) Arthrostylidium Rupr. Rachilla articulate and reatily separating at the joints; spikelets in racemes or one-sided spikes, these arranged in tufts at the culmnodes; leaves without distinct cross-reins. Tall shrubs and climbers.

Species twelve, in tropical America. The lowest culm-joint of A. Schomburgkii Mumro, which may be 5 m. long, furnishes the dreaded "blow-gun" from which the natives of Guiana shoot their poisoned arrows. A. excelsum Griseb., of Trinidad and Dominica, attains the height of 25 m . and a diameter of 30 cm . A. capillifoTium Griseb., of Cuba, has leaves as fine as horse-hair, 6 cm. long. A. ©uexo (Aulomemia Goudot), of Colombia, is remarkable in its loose panicles.
293. (279) Phyllostachys Sieb. et Zuecar. Spikelets in short, loosely paniculate spikes which have a very peculiar appearance on account of the large imbricated leaves covering their bases, 1 - 1 -flowered; empty glumes $2-3$; style one with three feathery stigmas. Stems arhorescent, semi-terete; nodes prominent and leaves nettedveined.

Species four, in Japan, China, and the Himalayas. The black-stemmed species cultivated in European gardens under the name of "Bemlusu nigre" Lodt., whose flowers are unkuown, probably belongs here. The graceful culms are used for walking-sticks ("peppercanes'").
294. (280) Athroostachys Beuth. Spikelets one-flowered, in dense, globose heads, sulbtended by enveloping leaves; empty glumes two, short; styles two.

Species one (A. capitrata Benth.), a suffrutescent climber of Brazil. Mouth of the sheath with long, stiff bristles.
295. (281) Merostachys Spreng. Spikelets with 3-4 empty glumes, the lowest of which is very small ; flowering glumes chartaceons; palea many-nerved, with the rachilla prolonged beyond it and occasionally hearing a bract; styles two. Tall shrubs or climbing plants, with leares indistinctly netted-reined. Spikes unilateral like those of the Chloridece.

Species nine, in Brazil, Paragray, and Peru.
296. (282) Chusquea Kunth (Rettbergice Raddi, Dendrogrostis Nees). Spikelets with four empty glumes, the lowest small and narrow, the upper like the flowering glume, the latter broad and awnless; rachilla not prolonged ; styles two. Small-leaved, tall shrubloy or climbing plants with terminal panicles.

Species thirty-five, all American; especially characferistic plants of the higher regions of the Andes and the Brazilian highlands from Mexico to South Chili, as far as Chiloë.
297. (283) Planotia Munro (Pletonia Kunth nou Mart.). Panicles very long and narrow, with small, very numerous spikelets having the same structure as those of C'husquer, but the habit of the plant is rather that of the Festucere, with herbaceons, almost leafless culms, and leaves crowded together close to the gromid. The rery long and often broad leaves are usually contimous (not articulate) with the sheaths.

Species five, in tropical South America, especially in Colombia. $P$. nobitis Munro has the largest leaves ( $1.5-4.5 \mathrm{~m}$. long by $8-30 \mathrm{~cm}$. broad) of any grass ; panicles over 1 m . long. Characteristic species upon the Paramos of Riuz. ["Paramo" is the name applied to the elevated plains of Colombia, etc.]

## Sub-tribe B.-Eubambuseæ.

Stamens six; caryopsis with a delicate pericarp.
298. (284) Nastus Juss. (Stemmutospermum Beauv.). Spikelets with 6-10 empty glumes which gradually increase in size and become above like the flowering glumes ; rachilla prolonged beyond the flowers; flowering glumes coriaceous ; ovary maked; styles $2-3$, more or less grown together. Tall shrubs with branches apparently in whorls. Panicle short, upright, or contracted into a head and few-flowered.

Species two or three, upon the Mascarene Islands. $N$. Borbonicus Gmel. forms a sharply limited wooded zone on Reunion Island, between 950 and 1300 m . abore
sea level, which is only here and there interrupted loy lava streams.
299. (286) Bambusa Schrel). (Bambos Retz, Ischurochloct Büse). Spikelets with 2-6 empty glumes gradually increasing in size and becoming like the flowering glumes,

Fig. 108.-Leafy twig of Bambusa arundinacea Retz. B, C, pieces of Tabasheer.
which are coriaceo-chartaceous, awnless, or with short mucronate points. The two- to many-flowered spikelets are frequently polygamous, especially the upper ones, and the lowest is often $\&$ or empty. Ovary hairy; styles 2-3, more or less grown together at the hase ; (aryop)sis elongated-linear, smooth or slightly furrowed on the inside.

Ustually tall arborescent shruls or climbers, with simple or componnd, rarely capitate, pauicles; spikelets in fascicles aloug the branches of the inflorescence. There are three geographically distinct sections:

Sec. I. Eubrrmbusc. Palea with projecting keels, which, however, are not at all, or only indistiuctly, winged.

Fig. 109.-Bambusa villgaris Wendland. Habit $\left(\frac{1}{2} \sigma\right)$. (After Maout and Dec., Traite de Bot.)

Species thirty (besides several which are known only by their leaves), all belonging to the Old World. $i$; Bulcoon Roxb. and B. Tulda Roxb, are esteemed as the
species most useful in East Inclia, especially the first, which becomes very durable after lying in water. Both are thormless. B. armulinucen Retz (Fig. 108, $A$, and Frontispiece) ( $B$. spinosu Roxb.) is a thorny and also an Indian species. B. vulguris Wendland (B. Thomursii Kunth) (Figs. 109, 110), with prominently nettel-veined leaves, compressed spikelets, and a long, hairy style, is frequently cultivated in the tropical zones of both hemispheres; its native country is uncertain ; it is also found in European green-houses. B. Fortunei Van Houtte (B. picta and B. variegata Sieb.) is a somewhat dwarfed species, with broadly striped leaves and transparent cross-veins, and makes a beautiful ornamental plant. It is from Japan, and endures the winter in Western Europe. B. nana Roxb. (B. glaucescens Sieb.), from Japan and China, is 2 m . high and has leaves that are grayish blue on the underside. There are other species having horticultural names but which are not scientifically classified.

Sec. II. (285) Guadua Kunth (as a genus). Keel of palea more or less distinctly winged.

Species fifteen, all belonging to the New World, known in Brazil $B$ as "Taguara." The same name is, however, applied to the Chusquere and Arthrostylidice.

Fig. 110.-Bambusa vulgaris Wendland. (After Kunth, Revis. Gram. pl. 74.)

Sec. III. GAuculuella Franch. (as a genus). Keel of the palea distinctly winged; spikelets strongly compressect.

According to Franchet the species included in this
section is only 60 cm . high, herbaceous, producing merely two large leaves on each culm.

Species one ( $G$. marantifolic Franch.), grows at Gaboon in tropical West Africa.

Fossil Species.-A plant from the middle Pliocene of South France is placed in this genus as B. Jugdunensis Sap., and perhaps correctly. On the contrary, the species described under Bumbusa of different authors are, according to Schenk's critical remarks, partly remains of Arundo and partly fragments of other species which cannot be classified. (Engler.)
300. Atractocarpa Franchet. Spikelets in loose, terminal racemes, very mach laterally compressed ; two empty glumes, then several of or sterile flowers, finally a $f$, terminal flower. Branches of the style conical at time of fruiting, broader than the caryopsis.

Species oue (A. olyraformis Franch.), on the Congo at Brazzaville. Accorting to Frauchet this grass grows only 30 cm . high, is herbaceons, and has ovate-lancenlate leaves 18 cm . long by $7-8 \mathrm{~cm}$. broad.
301. (287) Gigantochloa Kurz. Differing from Bambuse only by its monadelphons stamens. Tall arborescent species with mumerons, dense fascicles of spikelets in branched panicles.

Species 4-5, in the Malayau Peninsula and Archipelago. G. verticillutr Muuro grows to the height of 40 m ., with the branches besimning very high up on the stem.
302. (288) Oxytenanthera Mumro. Spikelets long, conical, in compact fascicles, with $\underset{\succ}{ }$ terminal flowers, and 1-3 o or sterile ones below ; empty glumes $4-7$, acute; lodicules none; anthers ending in a bristle or several hairs; fruit as in Bombusa. Tall shrmbs. Five typical species in the East Indies aud upon the Sunda Islands ; a sixth, forming the section Scirpolermbos, with large, spiny, capitate inflorescence ( $O$. Alby.simica Munro), abounds everywhere in tropical Africa.
303. Puelia Franchet. Spikelets in short, terminal panicles, otherwise as in Atractocrmpr, but with the
anthers grown together, and base of style persistent in fruit but not thickened.

Species one ( $P$. cilicta Franch.), at Gaboon in tropical West Africa. According to Franchet this grass is only 30 cm . high; culms herbaceous, with long, narrow-lanceolate leaves.

## Sub-tribe C.-Dendrocalameæ.

Stamens six; palea two-keeled; fruit fleshy or a nut.
304. (289) Dendrocalamus Nees. Spikelets in distant fascicles along the branches of the panicle ; rachilla prolonged beyond the uppermost flower; empty glumes two to many, increasing gradually in size ; lodicules noиe, or only 1-2 rudimentary ones; style long, with $2-3$ short stigmas, enclosed below by a beak-shaped prolongation of the ovary ; uut small, almost globose, beaked. Tall fruticose or somewhat arborescent, with habit of Bambusa.

Species nine, in East Indies, Sunda Archipelago, and China. D. strictus Nees, the "Nale Bamboo" of the English, in India, is one of the most robust and useful species ; it blooms almost annually and endures drought. The young shoots of $D$. Hamiltoni are a favorite vegetable.
305. (290) Melocalamus Benth. Spikelets two-flowered, small, in distant fascicles along the branches of the elongated panicle; rachilla prolonged and bearing a sterile glume. The lower flower only fertile; empty glumes two; lorlicules three, large; styles three, mited below; fruit globose, nearly as large as an apple, with a coriacenus, shining epicarp and "very large, fleshy seed." (Kurz.)

Species one (M. compactiflorus Benth.), a tall shrub in Martaban.
306. (291) Pseudostachyum Mumro. Spikelets small, one-flowered, arranged in spikes along the branches of the panicle, each with a sul)tending leaf. Empty glumes one ; flowering glumes acute, involute. Palea of the same length; above it there is a pedicellate globose or oblong
sterile glume. Lodicules three. Form of the fruit same as in Anagallis. Subarborescent.

Species one ( $P$. polymorphum Munro), on the Himalaya Mountains.
307. (293) Teinostachyum Munro. Differing from the 306 in the fruit only; spikes in tufts, short, densely flowered, appearing like elongated spikelets and so understood by Mumro. Shrubby or arborescent.

Species three, in East Indios.
308. (292) Greslania Balausa. Like the precehing, but differing in its styles and fruit. Fruit romedish-ohlong, with a thick pericarp which is full of holes. Shrubs 2-3 m. high.

Species three, all in New Caledonia.
309. (294) Cephalostachyum Munro. Spikelets sul)tended by an enveloping leaf ; rachilla prolonged beyont the fertile flower, bearing rudimentary bracts ; empty glumes 1-2; lodicules 2-3; style elongated, 2-3-cleft ; ovary and the elongated fruit beaked. Tall shrubs. Spikelets in dense heads, solitary, at the euds of the branches, or in many, remote glomerules; haring the appearance of a hergehog on accomnt of the bristly projecting subtending leares of the spikelets.

Species fire, in the East Indies and Madagascar.

## Sub-tribe D.-Melocanneæ.

Palea keelless, resembling the flowering glume.
310. (295) Schizostachyum Nees. Spikelets one-Howered, narrow-lanceolate, in remote fascicles along the branches of the panicle ; rachilla prolonged, the projection bristle-like; empty glumes 4-6, gradually increasing in size, the uppermost oue convolute like the flowering glume and palea, not keeled, many-nerved; lodicules 2 -3, narrow ; stameus free ; style elongated, 2 -3-cleft at the point; fruit a sinall ovate or globose, wrinkled nut, with a short beak. Tall shrubs with a slightly-brauched or simple inflorescence.

Species seven, in Malayan Archipelago, China, ancl the South Sea Islands, as far as the Sandwich Islands.

According to Kurz, Chloothemmus Büse, with norlding spikelets, also belongs here.
311. (296) Dinochloa Büse. Spikelets very smail, one-flowered, in distant fascicles along the branches of a very large panicle; rachilla not prolonged ; emptr glumes $2-3$, ohtuse ; flowering glume oue, similar to the empty ones; palea very broarl, fringed; climbing, frutescent plants. Fruit not well known, probably fleshy.

Species one (I). Tjenkorreh Buise), in the Malayan Archipelago.
312. (297) Melocanna Trin. Spikelets one-flowered, in crowded, one-siderl spikes, $2-3$ together in a tuitt which is subtended by a leaf; rachilla uot prolonged; empty glumes 4-8, mucrouate-pointed, many-nerved; loclicules two, narrow ; style elongaterl, 2-t-cleft; fruit shaped like an apple, fleshy. A tall tree.

Species one (M. brmbusoides Trin.), in the East Inclies, occasionally cultivated (on Manritins, for example). The fruit, which is $8-12 \mathrm{~cm}$. in diameter, is baked and eaten by the natives. The seed is the size of a betel-nut and of good flavor.
313. (298) Ochlandra Thwaites. Spikelets one-flowered, large, arranged in glomerules forming in interrupted spike, or in terminal heads; rachilla prolonged ; empty glumes $3-7$, coriacenus; flowering glume and palea involute, elongated. The numerous lodicules and the stamens somewhat commate at the base, the $6-30$ filaments either in several bundles or grown together into a tube that elongates after flowering; orary longpointed, style elongated, slightly 4-6 cleft at the summit; fruit as in precerling geurs, but somewhat smaller, acuminate-pointed or beaked. Tall shrubs.

Species three, in the East Indian Peninsula aud Ceylon.

Doubtful genera: Pentarhaphis Kunth and Polyschistis Presl (Choridere?) ; Lepturopsis Stend. (Audropoyonere) ; C'hutoisscert Fourn. (Festucrcere) ; Asthenochlou Büse, Lachochlor, Kampmannia, Disakisperma Steud., position undetermined.

Hymenachne Beauv., 76.
Hymenothecium Lag., 66.
Hypocotyl. The part of the axis or stem of an embryo below the cotyledons. Same as caulicle. The term radicle is often used in the same sense.
Hypogynium Nees, 57.
Hypophyllum. An abortive leaf or scale under another leaf, or seeming leaf (Gray).
Hystericina Ṅteud., 106.
Hystrix Mönch, 192.
Imbricate. Overlapping like the shingles on a roof or the scales on a fish.
Imperata Cyr., 44, 49.
arundinacea Cyr:, 49.
sacchariflora Maxim., 49.
Inarticulate. Not jointed.
Indian Rice, 88.
Indurated. Hardened.
Inflorescence. The disposition or arrangement of the flowers on the stem. 10.
Internodes. The portion of the stem or culm between two nodes. 2.
Interrupted. Broken at intervals.
Intravaginal. Within the sheath; applied to branches springing from buds which do not break through the sheath of the subtending leaf. (See page 2.)

Involucre. Bracts surrounding or subtending a flower cluster.
Involute. Applied to a leaf whose edges are rolled inwards.

[^0]:    * Important Literature :-R. Brown, General Remarks, etc., in Ter'mischte Schriften, I. p. 10i.-Palisot de Beauvois, Essai d'une Nouvelle Agrostographie, Paris, 1812.-Kunth, Revision des Graminies, Paris, 1829, and Agrostographitu sive Enum. Graminum, Stuttgart, 1833.Rüper, Beitrïge z. F'lora Mecklenburgs, 2 parts, Rostock, 1844.-Payer, Truité d'Organogenie de la Fleur, p. 701, Paris, 1857.-Düll, Flora d. Grossherz. Buden, and in Martius et Eichler, Flora Brasiliensis, vol. II. parts II. and III.-Eichler, Blithenduagramme, I. 199.-Hackel, Untersuchungen uber die Loticule der Griser, in Engler's Bot. Jahrb., I. 336. - Bentham in Journ. Linn. Society, XIX. p. 14, and in Bentlam and Hooker's Genera Plantarum, III. p. 1074.

[^1]:    * In the figures the entire infloresceuce is always designated by $A$, the spikelets by $B$, the empty glumes by $C$, the flowering glumes by $D$, the palea by $E$. Compare Fig. 90 .

[^2]:    * For details see Engler's bot. Jabrbücher, I. Bd., S. 33a.

[^3]:    * The stems are used by coopers for making the joints of barrels intended to hold whiskey or petrolemm perfectly tight. The tidal mud along the Delaware River for fifty miles bears a heavy growth of $Z$. aquutien (locally called "The Reeds"), tud the fruit furvishes the food of the Reed-hird, giving it the flavor for which it is so much esteemed.

[^4]:    * I cannot agree with Prof. Hackel in this disposition of Bealia (Figr. 4ive). There are several species of Muhtenbergin which have the flowering glume two-toothed, the awn arising from between the teeth, which certainly do not belong to the sub-genus or section Clomena. This sub)genus is best characterized by the broad, three-nerved and three-toothed second empty irlume. The flowering glame closely ellvelops the conical or ovoid grain. In Betlie the empty glumes are entire, subsequal, nerveless (or very faintly many-nerved), and the elongated grain is only loosely enclosed by the broad and deeply two-toothed flowering glume. The habit of Bealia somewhat resembles that of the typial ('lomenu, and I at first named it Mhhlenbergia Clomenoides, but the characters presented by the empty glumes, flowering glumes, and grain are so unlike the true Duhlenbergias that I can but consider it generically distinet.-F. L. S.

[^5]:    * The illustrations of the spikes of the Cereals are taken from the works of Mull-Guyot in the "Encyclopédie d'Agriculture."

[^6]:    * The portions here enclosed in brackets were written especially for the original by Dr. Brandis, author of "Forest-Flora of Northwest and Central India."
